that a connection request will go out to that port and then a 20 second timer is initiated and if there is no response within that 20 seconds it might send out a second one with a higher priority on the IP packet and that's supposed to help it get through routers and congested conditions and then if that one fails, we see the WinSock errors that there is a time-out.

M: [inaudible].

Michael Baldwin: In our classes we have a time-out available on a listen function and in our classes the listen function is called that because there is a WinSock listen and parameter is the number of seconds to time-out and when it's called, it's listening for a connection for as many seconds as are specified or indeterminately, and it's a good question for the FTP protocol, because with the FTP protocol there is a control connection and then there's a data connection. The way it works is the control connection connects to the host, starts a listener when it's time to move data or get a listing, starts a listener, and then tells the host, "Connect to me on this port," and then do it. It connects to the port and it's a good example of when a time-out would be convenient because you may only want to listen for 10 seconds or 15 seconds and then have it just automatically go away.

M: [inaudible].

Michael Baldwin: Yes, that's right.

M: So you're blocking during that time?

Michael Baldwin: No. Well, since you bring it up, I don't have it as part of this talk, but we'll talk about blocking for a second. The question is: were we blocking for all that time? There are three types of communication, how shall I say it, software mechanisms here. The first type is called a blocking synchronous mechanism where you'll disappear into the function waiting for something to happen, any event of importance. It was used widespread ...

M: [inaudible].

Michael Baldwin: Yes, sir.

M: Definition of blocking?

Michael Baldwin: Yes. How about if I do a quick change here to Tutorial 11.

M: [inaudible].

Michael Baldwin: This right here is tomorrow's 1:30 talk, and it's on my diskette so you'll get it on the CD-ROM. I'm going to drop it off with [the CD producers]. Software 101. Synchronous blocking functions. They capture your thread and return when the function is successful. That's the way communications was done on a UNIX because you had very nice multi-threaded, multi-tasking support under UNIX where you wouldn't interfere with anything else if you were doing that. So [in] a typical connect, for example, you could basically do a blocking connect into that function for a second or two and other things would still be happening on that machine; however, there were some problems there to do that under DOS or Windows.

Asynchronous, non-blocking function is one where you capture a thread but you return quickly whether you're successful or not. So under DOS that would be typical, if you were to write a RS-232 application under DOS, not under Windows but under DOS, you'd be stuck doing some type of polling mechanism seeing as the buffers fill and if you were to go to LAN Workplace for DOS, for example, who has a Sock library, that's a typical default behavior for that library. LAN Workplace for DOS that was bought from EXOLAN back a couple years ago that was one of the few ways you could program TCP/IP at that point.

With the development of the WinSock specification, asynchronous is Windows trademark, right? I mean, asynchronous, event driven, so the synchronous blocking function was quite bad, disappearing into a Windows call for a second and if any of you used Eudora's mail program, for example, when the hourglass comes up, it's an asynchronous blocking call. And that's typical of many programs that reported into the Windows environment from programmers who had code that was synchronous in nature, meaning that step 1, step 2, step 3 right in the code, okay?

The asynchronous non-blocking functions are the way to do it in Windows because what happens is you set the function, the connect or the send into action and then it will tell you when it can accept more data or after the connection is successful, so it's an event-driven mechanism. Our professional-grade libraries have to use completely non-blocking functions because it's an anachronism of the Windows environment in that only one blocking function was allowed at any one time, so if you ended up with application A using a blocking using a blocking function and application B using a blocking function, B would typically fail because the WinSock layer said, "No, no, no! I can't do that. I'm already in this peak message loop down here doing work."

Think of the answer to that a couple days ago when it came up and I don't know. I know it has to be the case architecturally for Windows for Workgroups, but with this machine here and Windows 95 and Windows NT, I'm not sure, it's still in the spec, but I'm not sure if the actual limitation exists. If one were to test it, but [this is] still, I guess, the only place I might say were you could live with that is if you're under Windows NT and you spawned your own thread. I mean, if you wanted to do it that way, but it's probably just as easy to go through the lowest common denominator which is completely event driven and just forget about the availability of synchronous blocking, or polling, for gosh sakes.

M: [inaudible].

Michael Baldwin: Yes. A blocking function would be if the default behavior on the WinSock specification, if you call connect to a particular address, the function will return after the connection succeeds or does not succeed, okay? And if you're trying to connect to a host in Australia over many links it could be a matter of 5 or 10 seconds. The synchronous non-blocking function does the same thing. You could mark the socket as non-blocking, call connect and it says [inaudible] call connect [inaudible] and check back every half second on a timer until you've succeeded. So that would be the polling mechanism. And with the asynchronous non-blocking mechanism would be, request a connect in a couple seconds, your Windows procedures called with the appropriate message that says you're connected now. So those are the three communication mechanisms all supported under WinSock.

M: [inaudible].

Michael Baldwin: Not really. Synchronous means that ...

M: [inaudible].

Michael Baldwin: That's synchronous blocking, but synchronous non-blocking is when you have to make the call but like you get an immediate indication so it comes out. It goes in and checks, then comes right out, so that requires a polling mechanism. And then the asynchronous comes in when you don't have to check and you're informed.

This is what in the TCP world has to happen to accomplish a connection, although you can take your pick on other protocols, too. Create a socket, something to talk to. Bind it to a port address pair. Set options and notification choices. Launch a connect request. There's another step you may have to asynchronously resolve a host name to an IP address, okay? That's what happens. And then if we're doing the asynchronous, which is what we do, we catch notification of success or failure and then you're clear to send or receive data according to the upper layer protocol being implemented. Examples of upper layer protocols are R-Shell, R-Exec, R-Log-in, Telnet, FTP, HTTP, all the products out here on the floor are based upon TCP for the most part, let me say 98% and then close the connection. And since it is a connection-oriented protocol, when one side closes the connection the other is informed of the connection closure.

M: [inaudible].

Michael Baldwin: Yes.

M: [inaudible].

Michael Baldwin: Yes.

M: [inaudible].

Michael Baldwin: The way it's implemented, let me hold the question for a couple slides, or one slide.

This is the definition of our TCP stream class and I'd like to talk about it from a design point of view, but it's really what most of this stuff is, I mean, once you get the design down, the coding just goes along. So with our C Power TCP class, the protected functions shown at the top are all virtual functions and we'll go through them one at a time here.

M: [inaudible].

Michael Baldwin: No. We do have a line of UDP-based classes that inherit from a UDP object.

M: [inaudible].

Michael Baldwin: Yes. Yes. Yes. Connect event is called by Power TCP to inform your application of a connection and the reason it has so many parameters is that it's the mechanism to find out what the remote dot address is of who you're connected to, the remote port that you're connected to, the local dot address of your host, the local port that your host is using and the local name of your host system, so it's a mechanism for finding out a lot of things about the local host. The receive event is called by the library when data is available to the application and you'll see there's a pointer to the data and the length because there could be imbedded nulls in the data for many protocols.

M: [inaudible] the application pro-actively goes out and says I want to read x number of bytes [inaudible]?

Michael Baldwin: That's a good question, we've thought of everything. Once a connection or even before a connection is established, we can call receive to set the max spike count and what that can act as is a throttling mechanism on the communications to the host and a good application of that, for example, is on our VT-220 emulator where there's a pause key. Ever been in an emulator and you [transfer] a 1 meg file by accident? Well, when we had the buffer opened up so that we would accept as much data as was possible on the machine, then when you hit the pause key a couple thousand bytes later it would stop, but when we set the max spike count to 80 in our emulator and then we hit the pause key and it sets the max spike count to zero, and all that does is it tells the library not to read any more.

M: The data's still just sitting there in the buffer waiting to [inaudible].

Michael Baldwin: That's right, and it provides back pressure, good lead in, this guy's great, it provides back pressure in the connection so that when you do a receive zero, stop receiving, your buffer fills up, so those IP packets are still coming from the host and you don't acknowledge them, they're dropped packets, then the host re-transmits later and so it provides back pressure. So what that does is, your buffers fill up and then the host times out so that starts relieving traffic on the routers and everything in between you and the host and it's called back pressure. It's relevant when you're running a 386 against a high powered HP, for example, in doing an FTP download. Your PC just can't go that fast and the fact that it's not handling the data as much as quickly as the HP, or whatever, is pumping it out, means that packets are dropped and not acknowledged, finally they're processed and then they're acknowledged and then they're repeated.

M: [inaudible].

Michael Baldwin: You get a blocking. It's called the send function on both the UNIX side and the PC side and if your local data buffers are full meaning that the recipient has not acknowledged the receipt of your local data, your buffers become full and then basically comes back to your application and will not accept any more data, so it comes up to the application level. That's a very good point for anybody ...

M: [inaudible] when you get that back pressure you're sending stuff and it starts to fail, you're going to have to put your own time-out back [inaudible] and try it again, right?

Michael Baldwin: That's true if you're developing yourself. If you're using our communication libraries ...

M: [inaudible].

Michael Baldwin: Thank you very much, yeah, we have it built in. It's called a send event, so what happens is send a pointer to the data, the byte count, usually [inaudible] is false and a D-word data tag. Let's say the byte count is 20,000 bytes, well, we know that that's bigger than the WinSock buffers, there's nothing that big. So what happens is, internal to our library, we send as much as possible to fill up the WinSock buffers and let's say that there's 18K left, we

make an internal buffer and fill it with the 18K of data as local copy, and then as it's spooled out over the WinSock, your application gets a send event with that data tag.

This data tag right here is the same as this data tag right here, so, for example, let's say you send out five buffers at 20K each, 1, 2, 3, 4, 5, and the data tag is 1, 2, 3, 4, and 5, your send event will be called and after a second or two with a 1, after a second or two with a 2, etc., until all the data is exhausted. So it's a verification and it's used for flow control. What flow control means is this back pressure thing, how are you going to manage the flow of data off your hard drive over the network.

M: [inaudible].

Michael Baldwin: That's right, right.

M: [inaudible].

Michael Baldwin: That's correct. It's optimization to try to send it out as quickly as possible.

A listen event is verification that a demon has been opened on a port and is listening so you get the local dot address of the port you are listening on and your name. Accept event is called when a remote process connects to your listener, so you get that accept event. An exception event is an exception mechanism. Basically it provides some error code information and description of something of an exception.

M: [inaudible].

Michael Baldwin: We have a number of protocols and perhaps we could talk about it later and I'll show them to you.

The connect function now, the public functions here are the functions your class will call. For example, to request a connection of the things of relevance are the flags, which allows you specified debugging or showing of information. The real relevant ones are remote host, remote port, your local dot address and your local port if you are a multi-homed host you may want to specify a local dot address, and if you cared or if it was required by the protocol, you would specify a local port.

For example, the FTP protocol specifies that the data port opened on the server should be 20 or 21, if memory serves me correct it's one of those two. If you're ready to accept a connection so in response to an accept event, you accept the connection, that's the second right there. To send data, we reviewed earlier, in order to listen for our remote connections there is a time-out parameter that a gentleman asked about previously and then we have a close where we can specify no delay or not which simply means whether an abort or a graceful.

M: [inaudible].

Michael Baldwin: Yes, it has to do with linger. Linger is a socket option on whether or not the close should be a graceful close that is acknowledged by the other end or a non-graceful close which just means you go away.

M: [inaudible].

Michael Baldwin: No. On the send, that information is not made available via the WinSock interface so that your application or our library doesn't have any control over the time-out.

M: [inaudible].

Michael Baldwin: And on the receive, if there's data there you're simply notified. You're notified if the max byte count is 1 or greater.

M: [inaudible].

Michael Baldwin: On the receive side you know the number...

M: [inaudible].

Michael Baldwin: The actual on the receive event, that's [inaudible] to the data and that's the byte count of the data, so that's what you actually just received.

M: [inaudible].

Michael Baldwin: Well typically you do not call receive. That receive is only for setting the max byte count because the way it works is, [as] the remote host sends you data within the class we know it, we make a local buffer and we pass down the information to your class.

M: [inaudible].

Michael Baldwin: Yes we do and if I had a UNIX host I could show you a very nice demonstration of how we connect up to an echo server and with a very small buffer size of 1 and as we increase the buffer size it just comes. It echoes it back very quickly.

Does anybody want to take a break? Okay, let's break at this point and we'll resume in, say, 10 minutes.

[Break]

Michael Baldwin: Welcome back from the break. I had one comment from the session who asked for some more examples. Would it help the group if I came up with some quick application areas for these classes? I had not originally intended that to be part of the presentation. Yes? No? Well, as we go along...

M: [inaudible].

Michael Baldwin: You want a link between an upper layer protocol and the TCP class? Okay.

M: [inaudible].

Michael Baldwin: Okay. Well, let me address the event handling. Is he coming back?

M: Yes.

Michael Baldwin: I'll hold off on that then. Let's talk about a driver class here that provides an added layer of software manipulation to the TCP class that we just described and this is called Telnet and most everyone here has probably used Telnet to log into a remote host.

The unique thing about Telnet is that the commands are embedded in the data stream so there is a functionality there that we have to do something with. We have to write some software that handles that functionality of imbedded commands in the data stream. The data has to be parsed and searched for sequences that must be responded to. And we make the note here most hosts will just halt communications if you do not respond to an event like do this option or don't this other option. It's called option negotiation. So if you thought of the TCP class here on the left, to the left of the raw data, that is throwing in raw data into the parser and you are to think of that as your Telnet class as the parser, then your Telnet class looks at that receive event that we talked about in the previous slide and searches for what is called IAC strings. When it sees an IAC string, it calls a command event with that IAC string or some representation of that string that one defines, and if it's data, then the data event is called and then you process the data. So there's a forking, if you want to think of it that way.

Telnet is an upper layer protocol that uses port 23 as a default connection, so after you create a Telnet connection just like you do a TCP connection, as a matter of fact the Power TCP class provides the connect member function that is actually called from the class that's derived from Telnet. Then the application needs to search for these control sequences and to respond to them, so that's the only trick to using Telnet — responding to these IAC sequences.

Now usually one would simply display the data on a viewer or in an edit box and our VT-220 special edit box, for example, actually interprets VT-220 escape codes and then performs that emulation right in the edit box and then when a user types in the edit box, typically that data is sent over the Telnet connection back to the host. Then the connection is closed when complete. So if one were to look at the typical Telnet session, we see that bullet one, create the connection you simply do a TCP connection on port 23 which is accomplished through the Power TCP class which is one class up. Then in the Telnet session we search for the control sequences and that searching is accomplished in the Telnet class because it's special, so this is specialization and then what is done to display data or send ASCII data is simply functionality of your application and then the close is accomplished just like a TCP close.

The class header definition C Power Telnet is derived from the Power Telnet class [and] provides private functions that are used for internal utility purposes. It searches for a string, for example. There is a command buffer that is specified and I'll point you at the receive event. Look where the receive event is called. The receive event is right here. On the receive event right there you see our derived class is intercepting that data and all the data comes in the receive event. Then what it does, depending on what's in the data there, it will either generate a Telnet receive event for your application in a derived class or a command event and that's the added functionality that it provides.

Now, what about the connect event, you may ask. Remember in the Power TCP class we had a connect event, well, this is in addition to that, so that exception event, the connect event and those other things are provided down in your class as well as this Telnet receive event and the command event. Then for added value the library by calling send command, you say what command you want to send, what option you want to utilize, sub-options string, and etc. So this is an example for using C++ class structure to add specialization and value as you derive classes. Now, in a previous slide I believe I showed a user class that was derived from this, any user class derived from the C edit box, so what you do when you do that is you marry communications to the visualization and make things very tight and very convenient.

I'm going to move on to FTP now. First of all for those not familiar with the protocol, file transfer protocol is a way to move files across the network and it does provide authentication support by a user and password mechanism. Most file manager features that you see like directory support, change of default directory, give a listing of the directories implemented. It supports both binary and ASCII transfers. A binary transfer is an exact image of

what was sent and an ASCII transfer is useful when some type of data is passed over the network where you want to know where the end of line is and the standard for knowing where end of line is over a network is a carriage return line feed for Telnet. So, if your UNIX host just has a carriage return end of line that's no problem. It changes it to a carriage return line feed over the network and then in Windows land we use a carriage return line feed to indicate end of line so that's why when you do an ASCII transfer of an ASCII file, the file is bigger when you get it because it's got the extra line feed on the end of every line. The reason that you really have to specify it is because if you have a binary file and it thinks it's sending it in ASCII, you can have unwanted data in it.

The benefits of FTP are that it's ubiquitous, the lowest common denominator in many cases of moving data across the network. The only competition it has in that category is trivial file transfer protocol or TFTP which is a UDP-based protocol that is implemented on many routers so you can typically TFTP to and from a router even when you cannot FTP to or from a router.

The drawback of FTP is it is inefficient for numerous files because practically every one requires a data connection for every single file and then you have a lot of overhead for generating all these data connections.

Now having said what FTP is, this is how it operates.

[Tape change]

Michael Baldwin: ...information over the control connections, so you log in. Create [a] TCP listening demon or server, so you tell the TCP object to listen. Is there a question?

So, right now at this point, we have a tele-control connection, now we have a listening demon listing at a port. Now we pass the address and the port of the demon for, there's a reason you have to do that, without having to get too technical, this is technical enough, right? When you pass the instruction for the file transfer, or the list, or he wants it more technical, pass instruction for the file transfer, like retrieve, RETV, whatever the file name that you want, and when that happens, then the host connects to your listening port as soon as it's connected and starts sending the data. And since you have orchestrated all of this from your client, you know what's going on.

So then you accept the connection, the host transfers the file data, or you transfer the file data, or the host sends you the listing data, the listing data that you requested, and you close the data connection, or the host does, when you're complete, and then you close the control connection and you're finished. And you can see all the messaging going on if you use a program like WS FTP, by John [Genove] on the PC side, it's kind of out in the public domain, and he makes all his mechanisms in the handshaking visible so you can see what they look like.

Now, this is on our entire FTP class, because there's like 30 functions underneath that, we're sending every possible FTP command, defined by the RFC. But this part up here is enough to illustrate the functionality, and when we have time, we'll go into the non-exposed part, for anyone who is interested in seeing that, to illustrate what goes on behind the scenes.

But, the reason this is a very good example of communication libraries, is because it abstracts, as highly as possible, something that is very much program-oriented and state-oriented, because when [do] an FTP, as we saw on the previous slide, log in, user name, send it to image type, listen up, send it to port number, retrieve the file, report the file.

So, as you go in to define your own communications library, it's called extraction, you need to extract to a very high level, as high level as you possibility can. The functionality of the protocol, so that when your user, perhaps you're an IS shop, maybe you're part of a... a very good example, you're working on a fairly big project, maybe you have four programmers and

then one programmer is designated to do the communications interface, and what he does, he extracts to a very high level, to provide an interface to the users of the communication stream and specializes it, to what they're trying to accomplish.

A customer protocol is sometimes used in the communications business, so that when this string of digits is received, the information is sent out. For an example if you wanted to make data base information available in a proprietary way, to people just in your company, you would want to hard code in some port number that you want to connect to and then you may want to extract out the type of information that you want into, like, ten types and then you just provide that interface to your users and they choose one of the ten types and they're in charge of doing the very nice [inaudible] machine interface and all those very nice things. But in your communications library, that's where the business gets done, and you're able to implement your proprietary protocol, just as these people here, back 10 or 20 years ago, defined upper layer protocols that caught on and became standards.

This is an example of a reference that's encapsulated, this gentlemen over here asked if he could see an example of how that's used. And the reason that it's encapsulated is because, up in the FTP control class, the FTP control class knows about the list, knows about the data connection, knows about the Telnet connection. So, the fact that we made him a reference, or we could have made him a pointer, by reference [inaudible], or because the reference always has to refer to an object. By providing that technique, we don't have to include a header file for the CFUP control class. So down here in this class here, that we've defined called Power FTP, within the library, we call control dot what ever the function is that needs to be accomplished.

M: So, does that mean that this class doesn't actually [inaudible] from the TCP class?

Michael Baldwin: That's right. This is an example of a class that uses an encapsulation technique with a control to keep private, but the description of the parent class...

M: [inaudible] it's already called back [inaudible]. You're getting the call..

Michael Baldwin: Exactly, so the mechanism here is when one of the, like the first procedure to be called is log-in. And [in a] log-in you say the name of the host that you want to connect to, and their user name and pass word, etc.

In our library, we get that. We say, oh, control.login, and provide the same parameters. So it's like a proxy if you will, it's between the user and the guts of it and the reason for doing that is so that your private HPP files don't have to [be] propagated everywhere.

M: So, [inaudible] but if you have the [inaudible] in the control class is implementing your [inaudible]. And then it has to somehow forward those messages back to your [inaudible], ITP class.

Michael Baldwin: Right

M: Does it have an [inaudible] to that, does it also have reference, also back to here?

Michael Baldwin: Yes it has to, and you knew the answer to that before you asked me.

M: I wasn't sure. I'm not a really big [inaudible].

Michael Baldwin: The connect event here, what happens is, and notice it's a virtual function, it looks just like our TCP connect event, but what actually occurred is up in that control class, the connect event was called, because it was derived from a Telnet class. And then all it does, it says, it turns right around and says, whatever it's internal name is for this class here, FTP.connect event, remote.address and so, that ties it together. Some people might use the term glue, you know, that reference to the control object, is to glue to this class here.

I understand ADA, that program language allows one to hide things by making them private and not having to replicate the HPP files all over the place.

M: [inaudible] The control [inaudible] transfers the events to [inaudible]. So it has to know you.

Michael Baldwin: That's right, and this goes back to what your previous point, that you can have these two objects talking to each other. This is an example of the reason for doing it that way.

M: Sure, but look at the [inaudible]. The control has to know the c [inaudible]. The c power is not derived from anything, so the [inaudible] base class, for which it knows [inaudible] events, how can it [inaudible] in it's constructive ... how can the control know the c power of the object.

Michael Baldwin: Okay. If you'll when the constructor of c power FTP is fired off, in it's, and I'll show this in the code a little bit later, after this session. But in the constructor for this class, it actually does a new and a C FTP control and provides a pointer to itself, this...

M: So the C P controls, expects in its constructor, the C Power [inaudible]?

Michael Baldwin: Yes, point to it.

M: [inaudible]

Michael Baldwin: So, in the constructor, to restate that, in the constructor of C FTP control, it's given two parameters, one the H instance, and right down here, that stands for internal reasons, and the other is a pointer to C Power FTP instance, which is called this of course. And then it saves that pointer, so there's a two way mechanism, so each knows about the other and it happens right in the constructor.

M: [inaudible] how the C FTP controls line [inaudible]

Michael Baldwin: Okay. If I was to do the alternative, which was, if I would derive C Power FTP from C Power Telnet, which is derived from C Power TCP, all of the data members in the C Telnet, in the C TCP and the C Power FTP, excuse me in the C FTP control, all those data memories would be exposed to the user. Because when a new C Power FTP happens, the object needs to know how big it is. When a C++ object is constructed, it needs to know the size of all it's data members and all the data members of everything it's derived from, so it knows how much space to allocate for itself. And the only way it can know that information, is if all the HPP objects it's derived from are included.

If you look at MFC, it's a very good example, and now you know why all those header files are in there.

M: [inaudible]

Michael Baldwin: This eliminates it, because the construct C FTP control, @, that means it's a reference, which means that basically it's a pointer, and the compiler knows that a pointer is only four bites long.

M: [inaudible]

Michael Baldwin: So the compiler can, when you drive your class from this and create a new, the compiler knows, okay, I've got to allocate four bites for control and whatever the data members are in the drive class and that's it at compile time. And then, at run time you say, new, see user FTP, it does a new on itself, so it knows how big it is, and then when it's the constructor of, and in the constructor of C Power FTP, we do a new C FTP control and dynamically allocate a second piece that's not part of the same object.

M: [inaudible], basically creating a C FTP control file [inaudible] within the constructor of C power FTP, you're creating an instance of C FTP control.

Michael Baldwin: That's right, and it's those dynamically created, it's a second object.

M: [inaudible]

Michael Baldwin: On the what?

M: [inaudible]

Michael Baldwin: Yes, destructors are almost, are always virtual. You don't have to state it.

M: [inaudible]

Michael Baldwin: I believe it's always, well...

M: [inaudible]

Michael Baldwin: I'll look into it, we haven't done it that way.

M: [inaudible]

Michael Baldwin: Well perhaps we can prove or disprove that after the session. Yes sir.

M: So basically, [inaudible]

Michael Baldwin: It's actually the client, it doesn't implement server functionality. And all the events, they are live events, whose upper layer protocol is a log event, that's used to inform the application of, actually data of, that was sent out to the host, for informational purposes. A receive event is used for spooling data over data connection directly to the application and for listing data.

A transfer event, we have an action where auto spool is an action, so that the library will take care of sending and retrieving data from with the library so that you don't have to do it. And the transfer event is very interesting, because like on some kind of a block boundary,

and every read boundary or write boundary in or out of the file, a transfer event is called, because sometimes...whenever see you're doing something and a little bar goes across, you know like a red bar or something, how much [of] the download occurred. You want to give some kind of user, feed back to the user when you're spooling a file of how it's going.

With [ply] event, FTP is full of these; particularly [when] you send it one thing and then you expect back something else. And so our way to handle that is with this FTP status indicator, that says, if it was expected, a part of the protocol was returned, so on the user side all they do is check for a success indication, instead of having check all the different numbers that could be coming back from the FTP server.

M: [inaudible]

Michael Baldwin: Yes, that was, like, if the FTP command was retrieve a file, that's just a little help back to the event, saying that you're retrieving a file remember, and that's the local file spec that you had specific. Or if was sending a file, it might have been store or store unique, or append.

M: [inaudible]

Michael Baldwin: Yes, and it's something to keep in mind when you make a library, especially a communications library, you can save state information within it, because you really have to, because many of these protocols are state machines.

So you save the state and then you simply volunteer the state information to the user whenever it's relevant. We have taken that approach versus another approach, where you can force your user to ask all the time for things, more or less on a polling-type nature. We have standardized on this model where the public methods are provided for you to call and none of the public members give you a way to get information, except for the state. And then with the events, this is where you volunteer information to your user and it greatly simplifies the life of the individual doing the coding on the implication side, because now he doesn't have to ever think about checking on status or states, as much as he simply starts things in motion and then is notified whenever something happens.

A lot of our customers are Visual Basic customers, a little different class of programmer. But, they really love the idea of this synchronous operation. I mean, I don't know how many guys do a log in and then he'll do events forever, waiting for something to happen, just so he can send a file, and then he'll do events again, just so he can close, just so he can have everything in a line right there. With Visual Basic, you search [for an event] driven mechanism with these events, I mean built right into the environment and all you have to do in Visual Basic, is all you have to do right here.

When something happens, what do you do? It's a terrific, it's a very releasing type of mechanism, because some of us going back more than 10 years, we're used to the idea of having an executive and you're writing the executive and making sure that everything is done correctly and on time and everything, and it makes the control mechanism, makes everything very complicated. Well, if you just throw up your hands and become entirely event driven and distribute like this, you have no executive, you are simply notified. And it simplifies debugging, and the control of the application, I mean 10 times.

So it's event driven nature is wonderful in C++, it's a little messier in C, because you've got call back functions, it's great in Visual Basic, and now in VB4 we have the OCX's. And we've even got a tool kit for Delphi, and the call backs are supported there.

So, a little of advice for anybody going out there doing communications, always do it asynchronous, always do it event-driven, never force a user to poll or call a function more than once to check on anything.

M: [inaudible]

Michael Baldwin: If you want to, under NT with our VT-220 emulator, we're starting a thread for every VT-220 session, within our [MDI parent] and each one of the windows is [MDI child,] and each one on it's own thread, so we're going to have the communications and everything on it's own unique thread. Typically you don't have to do that.

M: [inaudible] thread to handle the data transfer, [inaudible] the file transfer to go off and actually start another one [inaudible]

Michael Baldwin: It's possible that some FTP servers may allow that. The FTP servers that I test against break, if you try to do more than one file transfer at a time.

M: Do you have another class that we can see here that would substantiate [inaudible] transfer, that inherits from a TCP or TCP plus?

Michael Baldwin: For a data transfer?

M: Yes.

Michael Baldwin: Yes we do. We have, as I've shown here, it's up there in that control, right after the, and if you want to stay around afterwards, we'll show you the code that implements it, accepts connections and all that stuff.

M: [inaudible]

Michael Baldwin: What's the question?

M: [inaudible]

Michael Baldwin: The TCP class can be used with [both] passive connections and active connections, so either servers are [clients].

M: [inaudible]

Michael Baldwin: Well, one of the things that we have to do with the commercial library is provide, kind of like base lines. This one provides this functionally, this one does this, this one does this. Now, it's up to the user to specialize it, to do something just for his needs. So for example, in your application, you may be, want to write a demon and derive it from our TCP class and have him be a listener and have him actually hold a list of connected sessions with each one, or perhaps a different derive class providing particular functionally. I've got a guy back at my office right now, he's half way through writing a Telnet demon for Windows NT.

So we've got the one class, that's the listener, and then we have this other class, and he's a console window. And the console window has properties of a window and has properties of a connection. Then when the listener accepts a connection, he assigns the new

connection to this guy. So he says, new console window, accept new session, he's off and running. So, we build these classes, we specialize these classes to a job you want to have done and then substantiate them on the fly. Dynamic allocation is a great thing that C++ gives, as I mentioned as a strength of a language. Yes sir?

M: [inaudible] Do you have any kind of way of getting, say, one [inaudible] and one application with multiplex multiple connections off of that, or say for instance there's only four ports available in that machine, but I want another 20 users, I want multiplex [inaudible] users I need for those ports, [inaudible]. Do you have any classes that do anything like that.

Michael Baldwin: Well I think you brought up a couple subjects, one is how to multiplex under TCP. Multiplexing is typically done by the system, we take advantage of the system, because we can open up an listener for example, if we accept one connection, it's connection-oriented remember, so as people connect in, we have to have a unique socket for each connection. So, what that does, well we just multiplex, we had to, we didn't have any choice. Because there is no way that people can hook up to the same process, you can't have a three way conversation. Because we're a TCP, we are point to point, so the multiplexing occurs because of the connection nature.

M: [inaudible]

Michael Baldwin: Now the select call, the select system you're referring to, is a mechanism for finding out which port has data to read from, for example. And we handle that totally event driven and keyed off the WinSock function, because the WinSock function will tell us when there's data to be read. So we surface the data then down to the user class, using the class library.

So, if I were to draw a pyramid here, to use the same imagery, if WinSock was at the top of my pyramid and these classes were built all the way down to the user level right here, and each object interfaces to it's own window. So we have six connections. When data comes into one of those connections, the event is triggered and the data is propagated right down and shows up right here as a receive event.

M: All it says is, I accept this action

Michael Baldwin: That's right, you have to give back the other call. It's a very good question, because it shows the object-oriented nature of this object. A single object can only do one thing. A single object can make a connection and converse or a single object can listen for incoming connections, and that's the only thing that a single object can do. So when the connection comes in at the listener, he has to do: new see new, what ever the new class is. Dynamically allocate it and then assign it a connection and we have a mechanism for doing it, just assigning it.

M: [inaudible] somehow transfer the information, some kind of handle over that new class [inaudible]?

Michael Baldwin: Typically what we would do is, a listener accepts the connection, you would dynamically allocate a new session of a particular class, we have an example, and then assign it the connection and then once that is done, the protocol goes back and forth between those two objects. So the new one you instantiated, and then perhaps a second later, another request

for a connection comes in, you do and maybe you keep track of these new objects on a list, so that there's a mechanism for keeping track of this bag with all these sessions going on. And then one side closes and deletes itself. This could be quite elegant, where whenever the connection closes, it just deletes it's own object. It's really very interesting.

You have these objects that are dynamically created and they delete themselves when they're done. It goes back to the control issue. If you can ever [have an] object do it to itself, like delete itself when it's done, or what ever, then you've encapsulated functionality in your class.

I'm sure everyone's familiar with dangling pointers and everything, and you've got, it goes back to the executive idea...

M: [inaudible]

Michael Baldwin: Yes, in FTP for example, when the data connection is closed by the other host, or we have no more data to send over the data connection. We close the connection and then we have a confirmation of a close in our receive event. If a null has passed through the receive event, it means the socket is closed. Right there we do a delete this.

M: [inaudible]

Michael Baldwin: To delete this...

M: [inaudible]

Michael Baldwin: The alternative is worse, how do you know when to delete it. If you can't... if the object can't do it itself, it means that you have to have another object delete it. So you have to have notification to the other object...

M: I'm not arguing about the design, just that you triggered some event [inaudible].

Michael Baldwin: Okay, well, thank you, I haven't run across a problem with it. And the reason we can do it, is because notification comes from the system from a WinSock event, so that when we delete this and we unravel everything we are not returning to some object that referenced us.

M: [inaudible] and it wants to eventually close it for some reason, but then [inaudible] has already completed itself [inaudible]

Michael Baldwin: A good question. The way we handle that in the FTP class, is that [in] the FTP control class, there's a pointer to the data. There's a pointer to the data object, and when the data object deletes itself, it nulls out the pointer in the control, so the control always knows if that data object is there.

M: So, if you delete a disk, and it was reallocated somewhere else, some other thread, it can no longer [inaudible].

Michael Baldwin: If what was reallocated?

M: Well that area of memory, [inaudible] reallocated by another object, [inaudible] no longer be null.

Michael Baldwin: Oh, it's a pointer in the control.

M: Because that was the lead, right?

Michael Baldwin: The control is always there and within the control he's got a pointer to the data connection. And what happens is, when the data connection is created in it's constructor, it updates the control object with the pointer to itself. So that the control object knows when it's in existence, and when the data transfer all occurs, and then it delete itself...

M: It deletes itself, it doesn't delete the control?

Michael Baldwin: No, because the way FTP works, you always have the control object there and then these data objects come and go as you transfer files.

M: So there's always one out there [inaudible]?

Michael Baldwin: Always there's a control, because that's the one that logged in, remember, you had to log in with a user name and password. It may be used, may have used the term session. You have an FTP session while you're logged in, and while you're logged in, you can get listings and get files, and send files.

M: How does that [inaudible].

Michael Baldwin: Well, when you call the close function...

M: Okay, so eventually you do have to [inaudible].

Michael Baldwin: Or your application you would just delete your object.

M: [inaudible] some kind of object, kind of an accept [inaudible] and create other objects [inaudible] independent sessions. I understand that these sessions decide that they want to go away [inaudible], or what ever, and they [inaudible] delete themselves and go away. When we have a case, we have a server and we have ten connections, we still [inaudible] and we have to turn the server machine off to do backup.

What we really need is for somebody to go and say, tell each of the objects, the session objects to kind of go away and then we can finally go and close the accept objects [inaudible]. In other words, this is a kind of a shut down force, in other words, don't let the two objects that are [inaudible] decide, have the server have many... shut them all down kind of thing.

Michael Baldwin: At any point, the control connection can be shut down, or it can be more graceful and just not accept any more traffic and try to just finish up what it's doing. But in either event, the way we handle it, is if the control connection is shut down, we delete the listener, if it's listening, and we delete the data object if it's in existence.

M: Do you have multi-poll data objects?

Michael Baldwin: Well, the way FTP works, you can only have one data object at a time.

M: Because if you had some kind of larger server, [inaudible], you're talking about some kind of link list, or you would have to manage your own objects to know in terms of sessions what's out there, and then run through a list. Or, if somehow by shutting down the accept [inaudible] properly, does the other guys all go away.

Michael Baldwin: Well it would be safe programming practice on your part as the designer of such an application, that if you had a control connection, or some way to find out from a host, then a shut down was in progress, that it would clear up, appropriately. This is, you're not talking about a standard protocol, but the beauty of these tools, actually, that you can implement whatever you want.

M: I'm just trying to figure out, what implements [inaudible], multi [inaudible] connections, multi... we have some instances where we like to do that kind of thing. One server with a lot of clients connected and someone wants to turn the machine off to do maintenance, so you have to somehow systematically go through and notify everyone [inaudible].

Michael Baldwin: So the way you would do that...say you're port 2000 implements your proprietary server, that sends information. And then when you're implementing your protocol, some kind of signal, like star star star, that when ever it's received, notifies the client that there's five minutes to go. Or you could simply close the client connection, which would be the signal back to the client to release the resources.

M: If you had local clients [inaudible] you had multiple object substantiator, right?

Michael Baldwin: Yes, a list is typically the way you would keep track of it and ... Maybe, I could give you an example, of just that, we'll look at some [inaudible] here. (If you'll excuse me I'll sit down so I can see a little bit better.)

Here we have a tool kit shown that, we'll just run through the applications so you can see what it does, it's called an echo server. Now when I started this 16-day application, this is a C++ app, what we have shown here is an MDI parent window and we adapted the MDI parent, and did a double inheritance and a listing, that is actually, so we derived this class both an MDI parent and then a TCP object and sent listen and port 7. So, we see here [the] server is listening on port 7.

I'm going to run through a little demonstration routine and I typically use this for demos because it illustrates so much functionality. Before I do anything, I'll explain what it does.

An echo server is an application that accepts a connection and then repeats back whatever it receives, so it's very simple in functionality. But in order to construct such a beast, it's quite complicated, because you have to dynamically allocate resources to handle all the structures and information and the communications and all that stuff.

But how a communications library can make that easier is that we actually have them in an array, one, two, three, four, five of clients. They're done [inaudible] when we dynamically allocated this forum and this is [inaudible] back to it's creator, it's new and assigned to an array of link five, of [planners to] five communication matrix.

When I press test, what it will do, [is] it will tell each one to connect to it's own IP address so we're going to do a loop back over the, through the network layer, but we're going to use an IP address that is S on port seven. And then this listener here, there's a user class drive from the listener, whenever he gets an accept event, he will do a new MDI child window.

And an MDI child window is actually derived from two classes, the MDI child and also a Power TCP control. And then after it does a new, it says, accept and accepts a pointer to the listener and gets assigned the communications.

Then the total responsibility [of the] object is simply whatever it receives [and] sends it out. That's the entire functionality of that object. And the entire functionality of this thing where I press test, dual connection and then when I get a connect event, any of these are all the same class. So in this class if I get a connect event, I send this information. And then I try to send again.

So this happens very fast in this environment, [inaudible] you guys want to see it later, it's the new Gateway 2000 [inaudible] with a CD-ROM. It's a 90 megabyte, 90 megahertz Pentium, and just screams. But when I do this in Visual Basic on my 486, you can actually watch the things happen.

But, we have these file connections, and they are all on MDI child windows and we put up a new screen here what came in and then here on the other side [inaudible]. So, we'll showing the same thing each time.

[Tape change]

M: [inaudible]

Michael Baldwin: Yes, we have, actually, on this platform I I circuits allocated, one listening on port 7, these five objects over here, caused these five objects to be substantiated. And it's not very much code in Visual Basic, the actual network incurred here is about, or even in this environment is about ten different function calls or less. All the work is done just constructing the super plus objects that do behavior. When I press "test" here, it will close them all down and make five more... This is the first time I tested this on this platform, I'm surprised that it's working, I just got the PC last week.

Just to prove a point here, if I shut down this one, the other side is notified and [inaudible] in the window just as a custom feature.

M: [inaudible]

Michael Baldwin: ... but then again all the others worked, but that guy is no longer there. You cancel and it closes everything down. So that's our Echo Server sample.

We may have the network back up, so let's see ifIf we're up, this would really be great, oh, good.

Now this is my office back [home]. On my VT-220 emulator here, so I'll just cat et.test. That was my HP.

Here is my VT-220 emulator that shows all the characters and special thing. Okay, how would you guys like to see this in debug mode?

M: [inaudible]

Michael Baldwin: Okay, it's \$69.00. Go to our Web site and you can download a free demo. Okay, I linked all of my development libraries right at this point, so we can choose what we'd like to look at. But I think an interesting place to look would be [inaudible] CCP, this is, and you're all going to have to help me here. What would you like to see here? There's a huge number of things that we could show.

Remember before we talked, and probably very instructive, because it shows how a layer can be used to a particular functionality. So, this is our C Power TCP [inaudible]. We're not hiding anything here, it's all in there and the first thing that happens is, we see, we get data from the host, because we provide the body for this and say, if no buffer, meaning it's the end of communications, we do a Telnet event.

Remember that was the one way that we tell the drive class that there's data. Well, we do a wild count here and this is where we search for IACT, that we talked about before, so we go in here and do a code here to search for things, and if there's no IACT, tell it we see data, receiving that, there's a pointer to the data in the cat, there's I present, report the data and then strip out the IACT. So we put the data right there and then we put the IACT here in the command buffer and then we continue to process.

M: [inaudible]

Michael Baldwin: It always is and the reason that our [inaudible] library when everybody else does, is because we put it in this buffer off to the side. So that if we get a receive event, that is like breaks in our command in the middle, we've got this buffer off to the side that handles it. It's very robust.

M: [inaudible]

Michael Baldwin: Absolutely, this is it right here, check for a complete command, so we stuffed it in the command buffer and then we checked.

This is where we check for [inaudible] command and we do some searching and stuff. Then if it's a valid sequence, we call command event. So we make this, the implementation of this, we enforce the protocol and if it doesn't comply with the protocol standard, then we call an exception event, which is like what we did up here. [inaudible] it's a command event, if this condition's true, then we throw an exception there.

So all this code here is really not that much. But we've totally eliminated any of the other mechanisms that we had to worry about in the TCP class from this class. We just assume that there is a reliable string coming to us. And this is our second biggest revenue generator behind FTP, but it's cheaper, we actually sell more of this library than another, because it's so popular and used in so many places.

Let's find the end user [inaudible] application here. There's our [inaudible] size VT-220 sample and I chose to call this our Telnet Client, and you see right here we derived it from our Power Telnet and our VT-220 library, so multiple inheritance. And then these are the events that we have to worry about, key press event actually comes from VT-220. Connect event, receive event, command event and exception event come from the Telnet. There's a couple of private things there and that's the entire class.

If we were to look here at some of the interesting data, like command event, want to take it for a spin guys, did I hear a sure? I think I compiled this already in debug mode.

We'll capture command event when it comes in, live over the Internet. It's great these guys get me connected. Okay, here we go.

We've got our first command event coming in from my Telnet host in New York. Okay, we've got a 253 for the command, and the option is a 36 and there's no sub option, so we'll just step through here and see how the code handles it. So it's a do command and it's not a Telnet option, window size or terminal size. So we say we won't, we say, not, it won't.

Now, I don't know if we'll get another one, we did. Sometimes when you interrupt the real time communications, it doesn't continue. But this time, we get a do command, and it's one

of those options. 24, I'm not sure which one it is, might be terminal type, but we say, I will, at any rate, and then it comes down again, sub command, it was terminal type. So if it's terminal type, we want to be at VT-220 and the way we do that is you send a no VT-220, and this is a programming error, then should be another no on the end, but it probably works, I'll have to tell Paul.

Then we do another one here, and this was probably echo, that's a real popular one, you see a lot of.

Let's do something fun, I'll look at, [inaudible], so we move down to our power tone at receiving it, and it was right to here, we're going to go all the way down to my library, so that we have a library receiving it. And we'll call it Power TCP receiving that. You're seeing all my secret stuff now.

This is our receive function, well let's see how many we received, we may be able to see that, 58. That was 58 bites, [inaudible] received from the WinSock interface. [inaudible] this is way down the WinSock class. You'll see we had an event triggering our receive and handling.

So all this stuff works, and we'll turn that off. That was pretty effective, I wasn't sure if they were going to get the connections going for us here or not. So what do you guys want to see.

Officially we're done, but I'm going to hang around for anyone who wants to know more about this.

M: [inaudible]

Michael Baldwin: No sir, no, I don't booth downstairs, however, if you looked at our Web site, and I also have...

M: [inaudible]

Michael Baldwin: I do have some, a least a hand-out right here, if you'd like to take this. Give us a call, or access our Web site and you can see a lot of stuff there.

M: [inaudible]

Michael Baldwin: A windows socket is a standard that is specified and Microsoft complies with it, complies to that standard, and I can show you a real neat picture.

M: [inaudible]

Michael Baldwin: Does everybody plan to be here tomorrow, anybody not planning on being here tomorrow? I'll show you a quick picture. This is from a briefing I did to a bunch of people out at V Bits in Orlando last week, a Visual Basic program.

M: [inaudible]

Michael Baldwin: On the left we see a standard OS I model, which stands for Organization of Standards International, or something like that. Those are the seven standard layers of communications in writing software products. And the product that we're talking about, Libraries are pretty much session layer products. So if you develop your own library on the WinSock interface or whatever, it's a session layer product. In the TCP/IP mapping for upper layer protocols, the application writes for those three layers and then if you move, look over

here, our libraries really fall in the session area. So our code that you saw there, can be used by these different types of applications.

Now, I'm mixing my metaphors a little bit, but if you'll bear with me, I'll call this the WinSock interface, because that's a derail interface that defines how to access TCP and IP services from an application. And then the C++ class interface is right there and it just so happens that by deriving your user class, is the way you tie into...

M: [inaudible]

Michael Baldwin: Yes.

M: [inaudible] when you asked about connections, are these connections sources managed by the operating system or can you... do you have access to connections that are not open. For example can I write a software, another [inaudible] running on my server, and I want to write [inaudible] using your classes, [inaudible] any connections open [inaudible], any connections open and closing.

Michael Baldwin: No, you can't. Typically you can't keep an eye on that type of thing. The best you could do is intercept the WinSock DUL interface. Yes sir?

M: [inaudible]

Michael Baldwin: Yes, also. I lost my train of thought.

M: Okay I understand that, what you are saying is that the system [inaudible] that multiple access to these objects are objects that you created, only you keep track of those you created.

Michael Baldwin: They're pretty much tied to the task. So, if you were within that task and got the descriptor, then you could get information on it. There are some other mechanisms for getting information, I guess in NP. Typically, like get the number of packages being utilized. WinSock doesn't provide you... I think our UNIX, there's a way to get the status of all the open sockets of something, don't they have an application where the system manager can do that? Well, that would be like a, if that functionally is available, it's a proprietary interface to the operating system and not via WinSock.

M: Okay. The third question that I wanted to ask is [inaudible].

Michael Baldwin: Absolutely. Yes sir.

M: [inaudible] And I'm assuming that your power PC libraries, you [inaudible] all the different variances and nuisances [inaudible].

Michael Baldwin: That's a very good point, probably one of the biggest attributes from our customer's point-of-view, about our libraries that have been tested on over dozens of stacks and is working reliability. We do not test, explicitly test for a particular version or anything, but what has happened is over the course of time, we've located some stacks [that] behave a little bit differently. If an assumption that we make is not an assumption that they make, then it breaks. What we've done is we've just gone and fix it. We don't have to check, we've just become more defensive, more defensive coding, we've just added in where necessary.

M: [inaudible]

Michael Baldwin: At least for Microsoft NT, Windows 95 now, but you know they aren't perfect, I found a bug in Windows NT that drove me crazy, it took me a man day to fix it.

M: [inaudible]

Michael Baldwin: Yes, you see the standard is fixed, but the implementations are all different.

M: [inaudible]

Michael Baldwin: The question is what about WinSock II. WinSock II adds a couple of features, broad features. Number one, the protocol supports more types of protocols. And number two, actual features that kind of duplicate things that we already do. Under WinSock II you can give it a buffer, and say fill this buffer and tell me when you're done, very nice and event-driven. This is a very nice feature, that we kind, that's kind of like what we do for you, too. So it's a real good idea.

Now, where is it, it's two things, first it's the standard, so a body has to kind of make it the standard and then someone has to implement it, which is the second phase. And the standardization is not complete yet, and the good news is it's supposed to be backward-compatible with things that work today. So for example, we'll be obviously testing against the limitations to insure us through from our point of view.

Now, commercially, it could, if there's a commercial reason to do so, Telnet, our connect function may take another parameter called protocol.

M: [inaudible]

Michael Baldwin: Yes, just by changing a parameter on the socket call, what kind of socket do you want, an IPX socket.

M: [inaudible]

Michael Baldwin: The addressing will certainly change.

M: [inaudible]

Michael Baldwin: That's an interesting line, that's pretty detailed. Does anybody else have a general question, before I sit down and address that one?

I'm still getting used to the Windows 95. Let's go down to the basic clause, which is our [inaudible].

So, this window handler here called [inaudible] is a

M: [inaudible]

Michael Baldwin: Yes, in order to enable the event notification, we have to have a window, any kind of window, it could be a hidden window, it could be an MFC window, any kind of window...

M: [inaudible]

M: [inaudible]

Michael Baldwin: Yes, that's correct. It would be possible to show, but I'm not really sure why. So we have a socket procedure here, and notice that there's a member of our [inaudible] class, there is a [inaudible] end result, call back, socket pack. That means that it's a starter function, available to any member of the class and it's not associated with a particular instance. So there is no [inaudible] variable, that's important.

M: [inaudible]

Michael Baldwin: Good question, that's what you guys want to know. The socket is equal to get window, h wind zero. So in the NC create event, which happens very early on, we do a set win or something in the create [event]. And you probably all know where that is.

This is a creation of the window right here. So when we initialize the WinSock layer, we create a window, and when you're doing a C++ project, it's important to have two steps of construction. First is the C++ construction, where you don't really want to add too much additional overhead, because it's like really basic and the system takes care of it and returns a now, or a new if it doesn't work.

Then for any kind of object that requires additional resources, dynamic resources, like communication resources, you only have a second function, so that after the object is created, then you are stable and then you go ahead and respond more completely to any failures that occur.

So, after we create the object, we call initialize and it does nice things, like [inaudible] window class if appropriate. Then it creates the window, with H enhance and this. So, when the window is created, this is provided as parameter. Now, go back down to where we were.

The NC create call, the out parameter is a pointer and we reference the pointer, so we know, and that's for this. So, it gets set in the windows on, and then from every point it gets the window on for that window.

And then the socket object, close socket timer count, so everything is socket right or remote host.

M: [inaudible]

Michael Baldwin: That's a great question. Does an MFC have a C socket class? Yes they do. What does it do? Well it provides a thin layer to the WinSock functions. So it provides a wrapper, it's very thin, it's pretty much a one-to-one correspondence between a WinSock call and the call in the C socket class.

What does it add? I've had customers that, well one customer, he's a licensee of our FTP library but he's using the MFC class for the straight TCP connection, because it made sense to him, that's fine. The value-added that we provide, the testing and the maintenance and all that stuff, is important to different people for different reasons. For him, all he needed was FTP functionality, didn't want to take a couple of months to do it, so he licensed that. But for a straight string connection, he was satisfied with using the MFC class. It doesn't provide the level of things that we do for example, buffering upper data, that's still stuff that you have to worry about. Sequencing of things to do, still something that you have to worry about, but it's there. My customers are using it as well as our stuff at the same time.

It's not available to BVX yet, nor [inaudible], so people in environments that can use 32 bit OCX's, they can't use C socket. Probably half of my customers are in high level development, like Visual Basic and Delphi and about quarter of them are in C environment and about quarter are in C++ environment.

But the very high end users, they're in C++, or Delphi, the on-line people Delphi, they buy a 32 bit tool kit, there's some other vendors out here on the floor that you can buy tool kits from.

TUTORIALS

GETTING THE HANG OF UNIX

SPEAKER
Kevin Savetz
Computer Journalist

Kevin Savetz: I'm Ken Savetz. I am not an Internet guru. I mean, I'm an Internet guru, I'm not a UNIX guru. I am assistant administrator for North Coast Internet in California and I hope to explain to you guys some of the basics of getting the hang of UNIX.

The UNIX operating system has been around for a long time. It's the basis of a lot of what is on the Internet behind the snazzy graphics and the WorldWide Web. Most of the systems that are running on the Internet are actually UNIX systems. UNIX is basically a command-line interface which is not all that different from DOS, although it's certainly a lot more powerful in many ways. And a lot of the differences in how you use UNIX have to do with the fact that unlike using DOS or your Macintosh, UNIX is a multi-tasking, multi-user operating system and when you're on-line, there could be twenty other people or fifty other people using the same machine at the same time, so it shares the resources of the computer.

So, UNIX is very powerful, although a little bit more difficult to learn than something like a graphical operating system like Windows or Macintosh. I would like to get a quick idea of why you're all here so that hopefully I can skew this towards what you're interested in. I did this yesterday and about 90% of the people wanted to set up Web servers with UNIX and so I want to see if that's the case again.

M: I don't know [inaudible].

Kevin Savetz: Okay.

M: We're setting up the UNIX for our organization [inaudible].

Kevin Savetz: Okay.

W: I want also to set up a Web server [inaudible].

Kevin Savetz: Okay.

W: [inaudible]

Kevin Savetz: Background on UNIX? Okay.

M: [inaudible]

Kevin Savetz: Same thing? Anyone with anything novel or different?

M: I liked your book.

Kevin Savetz: Oh, thank you. Wow. Hey... Good.

So a lot of people setting up Web servers and people just wanting to get some background on it. First of all, up here is a URL. If you don't know what that is, you could leave.

We made a bibliography of Internet books, just four books, UNIX books. Four books that I happen to think are good introductions to UNIX.

In case you can't read my writing or you're listening to the audio tape which is available in the foyer, it's <http://www.northcoast.com/savetz/iwunixbib.html>. It's all lower case and if you can't read my writing you can ask me again later. I will certainly repeat it. Just four books that I happen to like that will get you going one step past this tutorial.

I think probably the easiest way to get started is actually to log into a UNIX system and to show you what it's like to log in and actually start moving around and creating some directories and some files and actually doing things. I'm using a Macintosh to log in, although you can use... I'm using Telnet to get in. You can use any conceivable machine on the Internet, or you might be actually sitting down at the console of the UNIX machine. It doesn't matter because it's all the same basic text interface no matter how you get in.

There are some graphical interfaces to UNIX such as X-Windows. I won't be getting into that. Basically that requires that usually you're at the console of the machine and most of us are just using text-based interfaces, so that's what we're gonna cover. Push the next button. We should get up on the screen there. I'm opening a connection... we can play with the lights maybe if you can't read that.

I am opening a connection to a UNIX machine at North Coast Internet in Eureka, California, although this could be a UNIX machine pretty much anywhere. I'm gonna see if I can bump up the size a little bit so I can read it a little bit better. When you connect to a UNIX machine, for instance by "Telnetting" there or sitting down at it, it says who it is.

This is a UNIX System V machine. There are a lot of different flavors or varieties of UNIX, we call them flavors. There's System V. There's BSD. There's Solaris'. This one happens to be running System V. Every different flavor of UNIX is a little bit different from every other and the commands might be slightly different; in one command "PS-EF" works to list everything that's going on the system and on the other type, it's "PS-AU." So the commands might be the same, but the modifiers might be a little bit different.

I'm going to try to keep with generic stuff that will work either way. Every UNIX system has manual pages that I'll show you how to look at later if you want to get detailed information about that system. I didn't want to use my normal account because I didn't want to mess anything up, so I created an account called "Hootie." When you log into the system, it asks for your login name and you type it in. It's usually all in lower case, but not necessarily; UNIX systems are case-sensitive in commands, in logins, in passwords, whatever. So, typing the command "LS" is probably going to give you an error because the command is really lower case "ls," for instance. I'm typing in my password, if I can remember it.

It's also case-sensitive, and it's going to think about that for a minute, assuming I typed it right. It tells me when I last logged in and asks for my terminal type. Not all systems do this and this one; a lot of them do, though, ask you for your terminal type. If you're going to be using a full-screen editor or one of the fancier mail programs that have a full screen and might clear the screen and do funky things, it needs to know what kind of terminal you're on.

VT-100 is a very common terminal type, so I will type VT100 and that way most things that we'll do will actually look good on screen. The next thing you'll see when you log into a UNIX system is called the "message of the day" or the "motd" and that's just this garbage that the system administrator thinks that you need to know to use the system, the system down-time being planned or something's running slow or whatever it might be.

Then to get to the prompt. In this case the prompt is "redwood" which is the name of the machine, followed by a percent sign. In most UNIX systems the prompt is the percent sign or a dollar sign. So now that we're here, we're logged in and, like I said, UNIX is a multi-user system so we can type the word, "who" to find out who else is on the system and to prove to

you that hey, there are currently four users on the system. You can even find out when they logged in and where they are coming in from. So here we are.

Probably the best place to start now that we're on-line is to start messing with files a little bit because I think that's what most of us — that's kind of what you work with. Files in UNIX are a lot like files in DOS except there's a mildly complicated permission system. Because since this is a multi-user system, it's not just sitting down at a DOS machine. Whoever's there can do anything they want. You can delete stuff. You can run programs or whatnot. In the UNIX permission system you can do things so that you can change or delete a program or a file, but other people might be able to read it but not actually write to it or run a program. Or you might make it so certain people can do certain things, or you might just have it closed off to the world because you're that kind of person and you don't people reading your stuff. So you can do that on a file or a directory basis and we'll show you how to do that in a minute.

The first thing we can do, the first command that I'm going to tell you about is "LS," [which says] I want a catalog of everything in this directory. It's like the "DIR" command in DOS or like opening a folder in Macintosh. Just see what's in there. You type "LS" and it gives you a list of everything that's in there. And I've created a little test file called "testing," and there it is. So, great.

UNIX file names, unlike DOS file names, can be very long. If you use DOS you're struck with eight characters and a three-letter extension. UNIX systems have a minimum of 32-character file names which they allow. Some UNIX systems let you have file names as long as 256 characters. It depends on the particular system you're using, but you can use pretty long file names. With 256 characters you can write a short letter to grandma just in the file name.

Also, UNIX files do not need to have extensions. A program is not necessarily going to have a .exe extension, although if you use extensions, they are for your own use. The system doesn't need them. It is very common for PERL, a programming language used in UNIX to have the extension .pl. But it'll still work. It'll still run if it doesn't have that extension, but it's easy for you to look at it and go, "Okay." Well, this is a PERL program because it has the extension. Or Hypertech's HTTP files generally have — or HTML files generally have the extension HTML or HTM, but they don't need to. The system doesn't care, but you probably will. So we've got this mystery file called "testing" and we want to know a little bit more about it. We don't know at this point if it's a directory or if it's a file, except that I just told you it's a file, and we don't know how big it is or when it was created or anything.

So we're going to use the "LS" command to find out some more information. And like in DOS, when you type DIR/W or something like that to get a wide view of the directory names or whatever, you can do that sort of thing with most UNIX commands. You can add tags to get more information or get the information presented in a different way. In UNIX you use the hyphen instead of the slash. So, it's "LS-" whatever. If I type "LS-CF" — actually this is a really bad example since there are no directories. Now we have a directory. You can see that the normal file which is just a file doesn't have anything after it. It just has the words "testing," but the directory says www/ and that slash shows you hey, that's a directory. So you can look at it at a glance and tell what it is.

The ls has a whole bunch of different things you can do with the output and the CF — which are, again, case sensitive — give you this particular format for output. Frankly, someone asked me what the capital "C" means and what capital "F" stands for. I don't know. It's just what you type if you want the output. And if you want to know more information about what each command can do, you can use the "man" command.

So we want to know everything LS can do. You can type "MAN" which means manual, space LS. And it will give you a very detailed manual page and a lot of UNIX systems, manual LS tells you everything you could ever possibly want to know about the command. And sometimes

it's just too much information. But this will tell us all about the LS command as soon as this thing actually comes up. The machine we're accessing is a little bit slow at all times. So LS lists the contents of a directory and as you can see here, there are 20 or 30 things you can do with "LS."

Have it list them backwards and sort them and do all sorts of funky things. So "LS-CF" gave us that information and now if we type "LS-L," this will give us long format. And this will give us all sorts of information about these files. You can see over here in this. In the final columns is the name of the file or directory, just like before. I'm going to work backwards through the columns here. The second from last column, tells us when the file was last modified. UNIX keeps track of when a file was created and when it was last changed. So it was changed at that time and this computer is on the West Coast, so the time is not the real time.

Third from last column is the size of the file. So we can look at this and say, okay, this testing file that I created is just under 65K. Here in this column we have who owns the file and since my login name is "Hootie," I created the file. Hootie owns the file. UNIX also has the concept of groups. You can be part of a group of users who might be in the same; you might be a group called "staff" which means staff members. Or I could be a group called "executives" which are the executives of a company. So group is based on your working groups. On this system, pretty much everyone is shoved into a group called "users" because we don't use a whole lot of groups, but imagine that there is a group called staff and a group called executives.

I'll show you in a couple of minutes on how to use permissions to make it so that the executives can look at a certain file, but the staff cannot. The second column with the one or the two is completely not important. I have asked a couple of different UNIX experts about what it's for. Nobody seems to agree, but everyone does agree that it's just completely... it doesn't mean anything to any of our lives. This first column with the cryptic dashes, "RS" and "WS" and that sort of thing tells us about the permissions of the file. And it tells us pretty much who can do what to the file. And those, of course, you can change if you have the permissions group.

There are ten spaces here. The first one... the first space here is either a dash or a "D." If it's a dash, it's a file. If it's a "D," it's a directory. There can be other letters there that mean obscure things like symbolic links, and we're not going to get into that. Basically, you're looking for a dash or a "D." And then we have three sets of letters. There's "R's," there's "W's" and there's "X's." The "R's" mean readable. The "W's" mean writeable and the "X's" means executable. Then there's three columns of that... RWX, RWX, RWX. Again, you get this information about your directory by typing LS, space, dash, L.

In that set of ten letters, the RWX's and all that good stuff, the first set of RWX gives you the permission for the user — if you've created the file, that's you. It's the person whose name appears there. The person who owns the file. It's what that person may do to the file. So, can the user, Hootie, read the file? Can the user, Hootie, write to the file? Can the user, Hootie, execute the file?

Reading means pretty much what you expect. Can you open up a file and read through it? Writing to it is can you delete or modify the file and the execute means if it's a program, can you run the program? And it's possible to set up permission so that you might have a PERL script or something like that that you could read the script, like look at it on-screen, but you couldn't actually run it. So that's for the user.

Then there's the user's group. Hootie is a member of the staff, so he's in group Staff. The system administrator sets up the grouping so a staff member can't decide that he's an executive and get into stuff he shouldn't be getting into. So Hootie's on staff. So, can the staff members that read the file, can they write the file, can they execute the file? And then there's others, and that's the final column of three. And others is everyone who's not Hootie and

who's not on the staff in Hootie's group, basically, and that would be the executives in our example. What can they do to the file? Can they read it, can they write it, can they execute it? And you can change these so that if you want to make it so nobody else but you can see the file, you turn off permissions for everybody else.

M: So, it's just dashes?

Kevin Savetz: That would be dashes, right? If the letter is there, then the permission is on. If there's a dash, then the permission is off.

M: So can Hootie, if he's part of the staff, let's say most of the staff can't execute it, but if you want Hootie to execute it, would he still be able to?

Kevin Savetz: The question was, if the group can't do something, but the owner can, can the owner do something? Yes. It kind of goes in that... the first column is totally dedicated to the user, and if the group can't do something according to permissions, the user can. Then, that's more important. So you can change those permissions and we'll do that in just a moment. Any more questions at this point?

M: You can have as many groups as you want?

Kevin Savetz: Yes, the UNIX system can have a whole lot of groups. There may be a limit, but hundreds and hundreds of groups. Some UNIX systems only allow each user to be part of one group. Some UNIX systems, generally newer ones, allow the system administrator to set it up so that you can be part of multiple groups. I'm not going to get into how that happens because I'm not even sure.

M: So the actual owner of the file could be cut out from being able to use it?

Kevin Savetz: Theoretically, yeah. The owner of the file could be able to write to it, but not be able to read it afterwards. And a couple of times as the system administrator I've had a user come to me and he accidentally changed the permission so that he couldn't read, write or execute the file. So it was useless to him. So he wanted the system administrator to fix that for him. That's also an important point, that the system administrator of the system and that user usually had the login name of a root, can do anything he or she wants to on the system and even if the permissions say he can't, he can read, he can write, he can delete, he can execute, he can run the program. He can do anything he wants to that file.

The superuser or root user is exempt from permissions on the system. So basically, if your employer wants to read your e-mail, they can. Something to keep in mind. So, let's change some permissions here and we're going to change permission using a command called "CHMOD," which stands for change mode.

Hey, our connection just died. I hate computers. Okay. Going to the back-up connection here. Ah, so you're going to talk to me. Very nice. Logging in again. Okay. Good.

So, the CHMOD command or change mode will let you change the permissions on files that you own. And you do that by typing chmod and then a space and then you tell it who you want to change the permissions for and whether you want to add or delete permissions, and then what permissions you want to add or subtract. I'm going to run back over to this again. It's easier to do over here. The pen is dead. Type CHMOD and then there is who and then what you're adding or subtracting and then the permission. And then you give it the file name. Okay?

So, we have to fill in these spaces here. Let's say that this is a file that I want people in my group to be able to read. So, I want to look at the first column. And the first column can be "U" for user, "G" for group, "O" for others or "A" for all. So in this case I want to add "read permissions" for the group, so I'm going to say "CHMOD G" for group. The second column can be a plus or a minus or it can also be an equals sign, so I want to add permission, so I'm going to "+," and the third column can be "R," "W," or "X." So I can say, CHMOD G PLUS R, that is group add readable to the file name and it will do that.

M: [inaudible]

Kevin Savetz: It's CHMOD, space, G + R, space, file name. And if I wanted to make it world-readable or readable by me and by the group and by other users, I can make this CHMOD, A + R...

W: [inaudible]

Kevin Savetz: With the equals sign, you can say "CHMOD A = R." If you're adding permission to something, it kind of assumes that you know what the permissions are. That is, you've taken the time to look. If you know you want it to be readable only, but nothing else, you can just type in "EQUALS THIS" and that's what it is without having really to know what it is already. For the first to the third columns, you can bunch letters, so if you wanted to, you could say... I'm going to be green all day, you can CHMOD "GO," that is group, my group, and others plus "RW" or "RWX," whatever. So instantly with one command, we've said that the group and other groups can read and write the file. It doesn't matter what order you do it in. You could say CHMOD OG instead of GO + RW or WR or whatever makes you happy. UNIX is not fickle that way.

M: [inaudible]

Kevin Savetz: Yeah, you could say "U GO A," although the "A" means the same as UGO, but that's fine, and + RWX... and that means anyone could do anything they wanted to the system and you'll come back the next day and some idiot will have deleted it. But, yeah, you can do that. There's another way to use the CHMOD command that involves a complex numbering system and frankly, that way's easier. Unless anyone really wants to know about the other way, you'll be just fine doing it this way.

M: Is that numbering system pretty much the same as [inaudible]?

Kevin Savetz: Yeah. If you know it, it'll work anywhere, but...

M: Where do you find information on that [inaudible]

Kevin Savetz: The books and the bibliography. I can talk about it if you guys want, but it does the same stuff as what we just talked about, and it's just another thing to write down — and this way's easier to remember, anyway, so... I don't see any murmurs of agreement, so I guess we'll just go on. All right.

This connection is evil. We're going to use the other one. Too many accounts and too many passwords and different screen names. Let's see if we have any files here. Okay. So I've a

file called "testing" I just created. Now on this system, and this really depends on how your system is set up, how the system administrator has done it, also you can change it yourself.

When I create a file it's automatically readable and writeable by me, but by no one else. The default on your system quite probably is different. On many systems when you created a random file it is readable by everyone, but... so anyway. This file is set up right now so that I'm the only one that has access to it, which is good. But this is a file that I want to share with everyone on the system, everyone I'm working with. So I'm going to do CHMOD, CHMOD, other and group plus read permission on file testing.. UNIX didn't say "okay." It didn't say "I understood." UNIX works kind of... I don't know. I think it's counter-intuitive sometimes. If everything has worked well, if it's happy, if it has no complaints, it doesn't say a word. It only says something to you if there's a problem, if you type something wrong or the file doesn't exist or whatever. So no response is good. No news is good news. Type LS, dash l.

The connection just died again. I do hate computers. Can you go find a Meckler person and tell them that Internet [inaudible]. I typed LS dash l and as you would have clearly seen on the screen, it would have been "R's" in all three of the readable columns.

M: How do you do that for a directory?

Kevin Savetz: On a directory, it's the same thing. You can just type a directory name instead of the file name. Directories are interesting creatures. If a directory is readable... we've been talking about files this whole time. Now, thinking about directories, if a directory is readable that means that the group or the others can see the files in the directory, can see the contents of the directory. They may not be able to look at the contents of the files because that depends on the permissions of the files. If the directory is not readable, then other people of the group or whatever, cannot see what the files in the directory are called.

However, if they know that something is in a certain directory and has a certain name, they can read the file if the file is readable. So, directories kind of have its own little structure.

M: How do they [inaudible]?

Kevin Savetz: Well, maybe you've told them what the directory is called and what the file is called. If you know that my directory is in "/user/hootie/testing," but user Hootie is not readable, but I've told you that file's there, then you can get in. Otherwise, maybe by guesswork. Other than that, people won't be able to... It's an odd situation. I'm just trying to explain how...

M: So if you get a [inaudible] command that hootie/, whatever...

Kevin Savetz: Yeah, user/hootie, right.

M: Will the directory that we don't have access to read come up?

Kevin Savetz: It would say "permission denied" or something like that. Unless you were Hootie and you had read permission, in which case then you could do that. Like in DOS — I wish I had the connection for this, but just imagine — if you've used DOS, you've noticed that when you type a directory at top there's a file called dot and there's a file called dot-dot. And just like in DOS, dot means this directory that I'm currently in right now and dot-dot means one directory up. So, if you want to change the permissions on the directory that you're currently in, you can type "CHMOD . A + RX," so that will let you change your current directory. The directory

that you start in, when you log into the system... you start in a certain directory and that is called your home directory. The system administrator sets up how that works. On a lot of systems it's /user/your login name. So, user/hootie.

On many other systems, on the system I administrate, it's files/home/hootie or whatever the login name is. You can find out what your home directory is by logging in and typing "PWD," which means present working directory. I think there's a thing in DOS that does that too, but I'm not sure. It'll tell you where you are. In fact, if you're moving around the system changing from one directory to another, which I'll talk to you about how to do in a moment, and you forget where you are, you type PWD. It'll tell you where you are.

To change directories, the command is "CD" for change directory, so CD space hello will move you into a directory called hello. You go into hello and you decided this isn't what you want. You want to go back up to where you were, CD space dot-dot will move you back up a directory. Hierarchical directory trees just like in DOS. However, something to keep in mind is that UNIX always uses in directories, forward slashes instead of back slashes. And that's something that bites DOS users quite often because you type, cd\user\hootie and the computer is not going to know what to make of that because you always have to use forward slashes.

If you type... This is the last thing I want to add to the LS command that we were talking about earlier. If you type "LS -A" or "LS-AL," if you like that long format, it will list all files; and when we were looking at files before, we've been deceiving ourselves in thinking that we're looking at all the files in the directory because UNIX has the [inaudible] for hidden files. Hidden files start with the "period" character and if you want to create a "hidden" file, you can create a file called ".hello," instead of hello, and then it won't be there if you type LS, but it will be there if you typed LS-l.

Unlike in DOS where hidden files are actually pretty darn hard to find unless you have Norton Utilities or also hidden files, you can't modify, unless you make them unhidden. In UNIX hidden files are not that secure. They're just kind of a way that you can get files out of the way, out of immediate view. For instance, there might be set-up files for your mail program. It might be .elm, if the program is called Elm. Instead of that, it might be called .ELM RC or some... So just stuff to kind of keep out of the way so they don't just bother you and you get them out of view. So, we've had LS-AL so you can see everything. You will see at the top the dot and the dot-dot directory and that's how you can find out what the permissions on the directory is.

The dot directory, the dot files or directory, you'll see the permissions just like on a file and you can find out hey, this directory is readable to the world or is not or writeable or whatnot.

W: Now does the user [inaudible]?

Kevin Savetz: The user? The system administrator. The user can make the changes on the files that he or she owns. You created a letter in UNIX?

W: But directory-wise.

Kevin Savetz: Oh, directory-wise. Certainly. But you can't change anything that you don't own. So, you can change the permissions on your home directory if you want to make it world readable. You can do that. CHMOD SPACE A + R SPACE DOT, assuming you're in it. But you can't change dot-dot or that anything you don't own. Other things you can do with files... hopefully, we'll get a decent connection. I can show you an editor so we can create a file. But once you have a file, "RM" [sets a] remove, and that will erase a file. So RM space testing and

hey... it's gone. Please take note, there is no undelete in UNIX. Once it's gone, it is gone. There is no way to get it back. There is no Norton Utilities for UNIX that will save you.

If the system administrator has bounced it off the tape and is willing to, he might be able to bring back the file, but don't count on it. So anyway, just be careful with the RM command. As with DOS, wildcards will work to RM space A* will delete all the files that start with the letter "A."

Also question marks work. Some UNIX shells, the actual interface they used, have a lot of other wildcarding-type things that are actually pretty advanced. So you can say, delete everything that starts with a capital letter or delete or list or do anything to do something to every file that starts with the letters "a" through "c" and have, an "n" or a number in there. So, UNIX wildcarding can be pretty advanced.

Oh, directories. To create a directory, it's "MKDIR." When you get sick of it later, the name is RMDIR... one word. So, MKDIR space WWW will create a directory called WWW and then to delete it again later, RMDIR. It needs to be empty first, otherwise it won't let you.

M: You don't forward slash [/]?

Kevin Savetz: No. No, you don't. My Internet connection... anytime, anywhere, it just dies after five or ten minutes. It's been really frustrating.

M: [inaudible]

Kevin Savetz: I tried two different sites in California that I have access to. If you can just get me into a UNIX system on site that won't do that, that's great. Thank you.

So, creating directories. UNIX generally has some common...

W: [inaudible] complete directory or do [inaudible] files directory?

Kevin Savetz: I believe you need a copy of the files in the directory. Yeah, and the copy command is "CP" which stands for copies. If you typed CP space hello space good-bye in the directory you're in, it will make a copy of it. As you might expect, you can also copy through a different directory. So, CP space hello space/tmp/good-bye will create the good-bye file in a completely different directory called tmp. UNIX systems have some common directories that you'll see after you've been on a few of them. Unlike in DOS where you might have — if you have twenty hard discs, there'll be C: D: E: F: .

In UNIX the system administrator sets it up so that it all seems to be one big virtual hard disk and it's not your concern what physical drive it's on. So, I guess the equivalent to c:\, just kind of the top of everything, is called the root directory. And that is the directory there is simply slash. Just one forward slash. Under the root directory you will find there are common subdirectories and how things are set up really vary from system to system, but you'll find a directory called usr. A directory called tmp where temporary stuff goes. A directory called "bin," where binaries will go. Programs like LS and CHMOD and that sort of thing. And it really depends on system systems. And we'll say that on our system there are usr tmp and bin. And under UNIX... under usr we might have all of our home directories. So we have usr hootie and we have usr john. And then Hootie created the www directory, so... and again, the neat part is it doesn't matter to you what hard disc [this] is physically on. Just do your work and go on with your life.

For the system administrator, the job can be kind of nasty because he needs to deal with what hard discs are getting full. He or she might have delegated the usr directory on one

physical disc and once everyone starts filling up the space, that person needs to deal with the problem. But luckily, you do not... so.

We have a file in ww called hello. If you're in this directory and you type CP space hello temp good-bye... pretend I can write. It will quietly copy the file to the directory temp a file called good-bye.

W: [inaudible]

Kevin Savetz: You can move files, too. And the command is "MV" for move. MV is just like CP except it deletes the original in the transition. So this will move a copy of a file to a different directory. You can also use MV to rename files. It's pretty much the command to do it. For instance, if we're within the same directory, want to rename hello to good-bye, you just type MV hello good-bye. ...this, for your purposes, hey, rename the file. That's all you really care about.

M: [inaudible]

Kevin Savetz: Because it doesn't. If there was a directory under ww called good-bye, it would actually move the file "hello" to that directory called good-bye. If it didn't, then it would say, hey, there's no directory here. It would just rename the file.

W: Would it still name the file "good-bye," or would it just...

Kevin Savetz: If there was a directory called "good-bye," it would keep it the same name in the new directory. Unless you said, MV space hello space good-bye/good-bye... which would mean move it to the directory "good-bye" and rename it to "good-bye."

W: So, [inaudible]

Kevin Savetz: That's correct. So you can use MV to rename files or to move files or if you're really creative or feeling self-destructive, you can do both at the same time. So we've created, removed directories. We've copied sets of directories. We've erased files and now we need to create files.

M: Before you [inaudible], in this example, if you copied it to tmp good-bye, good-bye or whatever, but you didn't have that directory, good-bye, would it create it then?

Kevin Savetz: No. If you try to copy to a directory that didn't exist... If you try to copy it to the directory, tmp good-bye good-bye, it will not create the directory for you. I have a couple of times mistyped a directory... I was just trying to move something with the same name to another directory, but mistyped the directory name and you end up renaming the file to the mistyped directory name. UNIX is very powerful in many things. This and other things. It's very powerful but it lets you bite yourself in the butt if you're not careful. So, you just have to be careful.

There are several editors in UNIX and just basically for creating files. A couple of them you'll find in just about every UNIX system. A couple of them aren't necessarily there, but your system administrator may have added them to the system. UNIX system editors are... none of them are very easy. Some of them are easier to use than others and none of them are as easy as loading Microsoft Word or just typing. The main UNIX editor that a lot of people use is

called "VI." It stands for Visual Editor. You figure it out. And VI is very common. You'll find it on any UNIX system. It's not so easy to use. It's moderately [inaudible], but it's very common and it's pretty darn powerful. Another very common one is EMACS and that's free software which is not installed by default on all UNIX systems, but it's very popular and pretty much any system administrator will have installed it on the system.

EMACS is very powerful, moderately common and in my opinion, really hard to use. I tried to learn it a couple of times and I just gave up and went back to VI. But it's very powerful and it does searching and replacing, and you can do so much with EMACS. In fact, EMACS is actually an entire programming environment and if you want to play games within your word processor, you can do that with EMACS, so it's a very, very big, complicated thing.

And the other one that I'm going to talk about is called PICO. PICO is less common, but really easy to use. It's really intuitive. You just start to type. You don't have to go into insert mode and there's always commands at the bottom of the screen.

Have you ever used WordStar or any of the... you want to save, there's a little row of commands at the bottom. If you want to save, you hit Control-S to save and if you want to quit, you hit Control-Q. And there's actually commands on the screen to remind you of these things which is not really true with the other editors. Thankfully, this is not a UNIX editor tutorial because I would die and you would die of boredom.

M: Is PICO a [inaudible]?

Kevin Savetz: PICO is part of the Pine mail distribution package, and is freeware. And speaking of mail distribution packages, I'll talk quickly about some of the e-mail programs that are out there.

Pretty much every UNIX system has a program called "mail," and usually that's a very simple mail program that will let you read your mail, send your mail, but it's a command-line interface and not all that user-friendly. No on-line help, but it does the basics of letting you see what e-mail you have from users of that system or from the Internet. On many systems are the two other very common mail packages.

One is called Elm, like the tree, and one is called Pine, also like the tree. Elm and Pine are both kind of full-screen graphical e-mail clients. Basically, they are menu-driven. There's a lot of on-line help. They're just like... just hit "M" to send a message and then it prompts you and asks who you want to send it to. You type the address of the first subject. It kind of walks you through it. Elm and Pine basically... try them both. See which one you like better or if there's [inaudible] on your system and not the other, well that's the one you're married to. I happen to like Elm better. A lot of beginners like Pine better.

Any questions at this point? I'd like to take a five-minute break for stretching or whatever and get some tea and then we'll come back and move on to something else. Our Internet connection, he's basically said that it's going to be flaky and we can use it for short periods of time, but it might die at any moment. So, I'm just going to try to not do that and it'll probably give us a little bit of extra time for questions at the end, so think up some. Somebody back here had a question when we were leaving and I was going to... I just don't remember what it was now. Okay.

M: I wanted to know as an executable file, how to find it.

Kevin Savetz: Oh, right. Does the executable... you type Elm or Pine or whatever program you're going to write, does it have to be in that same directory as you? And the answer is no. Like in DOS, UNIX has the idea of a path in certain places, and the computer will look when

you try to run a program that it can't find in your directory. The system administrator generally sets up a path for everybody which looks into basic places such as `usr bin` and the `bin` directory, and a program's connection can be spread out in multiple places.

If you want to change your path, you can do that as well. If you create your own directory somehow that you want to put binaries in...

M: [inaudible] in browsing the Web?

Kevin Savetz: The question is about CGI BIN, the CGI BIN directory. The CGI BIN files are programs that people on the Web can run. All the cute things that you see on-line where you get updates every ten seconds to something or a thing called "foam bath fish time" where — it's a clock and little bath toys. Things that you can do on the Web are done with what are called CGI BIN scripts, and that's a separate directory on the system where those programs are. And usually those programs are world executable.

However, in the specific instance of CGI BIN, they are... there can be a security risk because basically anyone in the world is going to run this program, so a lot of assistant administrators kind of clamp down and make sure that you can't put stuff there willy-nilly. So, does that answer your question a little bit?

M: Do I have [inaudible]

Kevin Savetz: They have to, right. If you have a program that you want to be executable on the Web, it has to be generally in the CGI BIN directory. There was a question back here.

M: I'd like to take a step back. How do you load Elm or Pine on a system if [inaudible]?

Kevin Savetz: If it's not on your system at all? It is the job of the system administrator which I — that would be you — to find the package. I was going to do this later, but this seems like a good time. When you're installing anything... Elm or Pine or hey, you're putting up a Web server and you need to actually install it, there are several steps involved in that.

The first one, as you might expect, would be to find a program, to choose one to use. If you know you're looking for Elm and Pine, then that's easy. You just use *Archie* or whatever to find it.

But often times hey, I want a Web server or I want a mailing list management program for UNIX. But I don't know which one. And picking the right one is often your real first task. The way I do that is I check UseNet news groups talking about that particular topic. I won't be able to get it right, I'm sure, but there is a UseNet news group just for talking about Web servers, `comp.sys.web.servers` or something like that. I don't recall right now.

Basically, start reading and seeing what people are complaining about and what people like. Also, use the WorldWide Web, *WebCrawler* or *Yahoo* or whatever your preferred search tool to search — most of these tools have pages that will detail the benefits and downfalls of each different package. Specifically, mailing list programs we were just talking about earlier. Looking for one, and there's basically a big table that says "Here's what *ListServ* will do. Here's what *MajorDomo* will do. Here's what [inaudible] will do." And based on that, I'm using a mailing list program that nobody's ever heard of called *SmartList*. But for my needs, it's very powerful and it does the job.

So you find the program you want and generally, as I said, there's a Web page out there somewhere that will help you choose the right thing for your needs. And you have to download to your system and that involves FTPing it to your UNIX system. FTP from UNIX... you run the

FTP program and you just type FTP space where you want to go: aim.stanford.edu. And then — I'm sure most of you are familiar with FTP. It asks you who want to login is. You type "anonymous," type your e-mail address as your password and then once you're in FTP, if you ever use [inaudible] spoiled by [inaudible] on the Mac or FTP graphical clients on Windows, you know what text-based FTP looks like and you'll notice if you've done that it's very, very UNIX-like. You type LS, you get a directory. You can type cd space whatever to change directory.

So, step two is you go to the site, you download the software to your system. Use the "get" command in FTP and now you have this big file of stuff on your system. Some programs are available in pre-compiled binary form. Those are good if you can find them. They'll end up saving you a lot of work.

Some, however, are available only in source code format. That is, raw C code or whatever that you are going to need to compile before you can run the program. I suggest looking around and if you want to save some time and you're not doing any really fancy customization to try to find pre-compiled binaries for your system, it'll save you a few hours of frustrating time trying to compile. The problems with pre-compiled binaries is they are not available for... sometimes they are not available at all. And often times when they are available, it's only for the major systems. You can find them for Solaris and maybe [inaudible], but you won't be able to find it for Joe Bob's UNIX company, for UNIX implementation.

So if you have something that's not one of the big three or the big four, then you might have to compile it yourself anyhow. So, you get your program and when you download a big program such as Elm or Pine, we'll say, you're going to notice the file name looks something like this. It might be, let's say, Pine. Pine-distribution.tar.z. A made-up file name, but it'll look something like that.

So, you've downloaded Pine and in your directory you've got "Pine dash disc dot TAR dot Z." Looking at this file name you can tell that this file is compressed and it's also an archive. If you've ever used [the] PKZIP program on DOS or StuffIt on the Macintosh, then you understand the idea of an archive and of compression. Basically, it takes a bunch of information and shoves it into a small space. It also gives you the ability to take several different files and put them into one file. Just [for] ease of distribution and transport on the Internet. In UNIX, the UNIX COMPRESS tool only does compression and the UNIX archiving tool only does archiving.

So if you used ZIP, you know that it will do both, but under UNIX it's two separate things. That's why we see the dot Z... a dot capital Z means it is compressed and the dot TAR means it is archived. So now we have this program and we want to turn this into something useful, so at the prompt, which I'm seeing is the dollar sign here, you type "UNCOMPRESS file name." It's a capital Z. And it will uncompress the file. And as always it won't say success or anything. It will just very quietly do that. And if you type LS again at that point, you're going to see that your file is called... it's going to rename the file so it'll be just pine-just.tar. It's not compressed anymore, so it takes away the dot Z extension for you. Now we have a TAR file which is still a big messy tape archive... that's what it stands for although we're not using tapes. It's just an old program called tape archive.

Now we have this old thing called TAR that we need to untar or unarchive so it's a whole bunch of little programs and files instead of one big one. So you're going to use the TAR command to extract the archive.

M: [inaudible]

Kevin Savetz: Pretty much any system you can possibly be at that's UNIX will have the uncompress and the TAR commands. So TAR is an amazingly complicated program and I don't

know what all these things mean. I just know that this works if you want to uncompress — rather unarchive — something, TAR space dash XFVMO space the file and then it will give you output as it creates information. In the specific case of Pine, Pine is a huge package and it will take up 15 megabytes of disc space and source code and all these directories and it makes a big mess on your hard disc. But that is the command you use to untar something.

Very recently, in the past few months, a new compression scheme has come up for UNIX systems and it's taking a foothold, although it certainly hasn't taken over the very common dot capital Z compression scheme. And that system is called "GNUZIP" and if you see something that's filed dot GZ, then you know it's gnuzipped.

And if you want to install packages, mailing us programs or Web servers or whatever it is, you may come across dot GZ's. Luckily, it's better... it's a little bit faster. It has a little bit better compression, but what affects your life is it is a compressor and an archiver in one program. So you get to save a step. Oh boy.

So if you've filed that GZ, you can type GNZIP file dot GZ and it will uncompress and unarchive the program in one fell swoop.

M: Where will it end up? I mean, can you direct it to a specific directory or will it just [inaudible]?

Kevin Savetz: Generally, with either TAR or GNZIP, it will end up in directories underneath your current directory. So usually when I download something, I create a directory called "working" and any garbage that the archive gives me is all safely under the working directory. That's pretty much a good way to do it. And then you can move it around. But at this point we're talking about source code or even if it's binary stuff that needs to be installed and most of these big packages have an installer and it will put stuff itself where it really needs to go down the line. So you type GNZIP and you have created a whole big mess of files. Quick tangent.

If you want to compress something with the old style compression, you type COMPRESS instead of UNCOMPRESS and so compress space file name... it'll compress it or rename it to file name dot Z.

If you want to zip something with gnuzip, you can type GZIP and it'll tell you how to do that. COMPRESS and UNCOMPRESS are pretty much available on any UNIX system; however, GZIP and GNZIP are not necessarily there and if you're the system administrator, the first time you may have to get it. But it's pretty popular and pretty easy to find if you use the standard in that searching tool.

So, we've uncompressed it, we've untarred it or done whatever we need. And now the fun begins because now you have to figure out to get the sucker installed on your system. If it's pre-compiled binaries, there is probably a program, an executable called install or READ ME or whatever. So, you read the READ ME, you run the installer, you do whatever you need to do and it puts it in the right place. If you've gotten source code, you need to compile it yourself. I'm not going to get into that whole big mess.

The most things that you'll get in source code on UNIX or in one of two languages, they'll either be in PERL or they'll be in C, spelled "C." Those are the two big languages. You'll find others, but not often. If you need to make something out of source code, generally you'll find a file called "Make file" with a capital "m" and that's where you'll find the things that you'll need to modify to your system. System specific stuff. You might need to know who the system administrator is or just system specific things that need to be in the program itself and the reason that they couldn't give you pre-compiled binaries. So you look at the Make file and then you type "MAKE" and it starts to compile and come back two hours later and you find that it's done and nothing has gone wrong. And then you wake up from your little dream world.

So, in a nutshell, that is how you find and compile and get something installed in your system. As I said, for the major packages, they're pretty easy. Either they're pre-compiled or they have a nice little installer that does the hard work of figuring out your system with specific system information for you. Smaller programs might not be distributed as well. You might just get [inaudible] files and do it yourself. I know a little bit of C and I just generally throw those programs out because I'm lazy and it's a lot of work to get some things in stalled, so...

Any other questions at this point? Okay. I'm not sure where to go next, then. Not having a computer in front of me has thrown me off my track. There is... let's see if I can login and I'll show you a little bit of GREP. Now is the time when I show you random other UNIX commands that we don't fit neatly into anything else. Thank you. I'm doing this very quickly because this connection will not last that long.

I showed you the WHO command earlier; it shows you who is currently on the system. FINGER is an Internet tool that you may have heard of in its own right which also, by itself, tells you who is on the system. You can also use it to find out who is on other systems. If you know that... hey, you want to know, someone gives you their e-mail address or you just want to Finger a site, a can type "FINGER" and the address and it will let you know about a particular single user on another site.

So "FINGER" by itself tells you about who is on your site. Finger address at another site will tell you about a particular person at another site. Let's see if I can bump the size up of this just a little bit. So I just fingered one of my accounts and you can find out the information that I have put up there. Now this is pretty basic Finger information. The login name, the person's directory, their real name and when they last logged in and sometimes if they have any unread mail. It'll put that in the Finger information.

Now, there is a bunch of information that I put there, not the computer. And this is called a Finger file or a Plan or usually dot Plan. And that's a file that you can edit yourself and it goes in your home directory and it's called "dot plan," all in lower case, and if you create that file and enter — our connection has died again — you can put information up there about who you are, what you do, anything you want and that's kind of a nice way to say "hi" to the world. And so if people are looking for you, they'll find you.

Again, in your home directory, it's called "dot plan." It's one of those hidden files. That's why it starts with a dot. And after you make one, you need to make it world readable because people out in the ozone are going to be looking at you so [inaudible] and that way you can just get the full information about you. Another useful UNIX command is called "GREP." It stands for something really obscure that I can never remember.

GREP is a way to filter through a file, to pull out particular lines with particular information. For instance, you might have a text file with a list of people's first and last names. You can use the GREP program to go through that file and just show you everyone whose last name has "Smith" in the name. And the way you do that... and GREP is just about on any UNIX system that you'll ever, ever come across.

So if you have a file called "test," you could say GREP smith test and it will go through the file called test and print out on the screen any line that has the word "Smith" in it. This is case-sensitive as always, so capital Smith will give you everything with a capital Smith in there. GREP is one of those commands that you can do 30 different things with. It's pretty powerful; GREP dash V, a search thing and a file name, does reverse and it will give you every line that doesn't have a particular line in it.

M: [inaudible]

Kevin Savetz: Yes, and I think you have to put it in quotes if you're searching for a phrase. So now, you type `GREP Smith test` and it just gives us the 300 names of people with the last name smith who came to the Internet World Show. That's not very useful on our screen because we want to do something with that. UNIX has the ability on any program, you can redirect the output to another program. And that's a neat thing about UNIX is that every command is actually a program and if you don't like the way it works, you can rewrite it, but the nifty thing is so you can take [output out] of a program and send it to another program.

So, there's a program called "`SORT`." So you could say, `GREP Smith test` and we can send it to the program, `SORT`. And the way you do that is you use the pipe, the vertical bar character [|] — sometimes it has a break in the middle of it. It's called the pipe in UNIX, so "`GREP space Smith space test space |`" to another program. So we want to sort it. Hey, there's a program called `SORT`. And now it'll dump to your screen a list of alphabetically sorted names. In this case if it's first name, comma... if it's first name space last name, it will actually sort them by their first name because it's just sorting alphabetically like you told it to. If you didn't like that, there's a program called "`CUT`" which will cut fields out of text files so if you only want to see the last names, you can do that. You can mess with information in a whole lot of different ways in UNIX.

Another way that you can use Pipes to do things is you can run a program and instead of sending out [inaudible] your screen, you can mail it to yourself in e-mail. This morning I wanted to run a program that I knew would take a couple of hours, so I typed the program name and I typed in "`program`" and I piped it to `mailsavetz@northcoast.com`. So it ran the program and instead of dumping it to my screen where I didn't really want it, it would mail it to me and I could just deal with it later next time I logged in.

Oh, a very simple and useful program is called "`CAT`" and it stands for "Concatenate." Concatenate is an obscure word which means to append things to one another. In its most simple — I am a grammar person, you can type `CAT file name`. That just dumps the contents of the file to your screen, so you type "`CAT space test`" and if test is a list of ten names it'll just put them on your screen. The reason it's called `CAT` is because if you had test, test 1, test 2, test 3, you could type `CAT space test one space test two` and it would put them all on your screen in a row, appending them. If you want to print, assuming you're at a computer that can, a UNIX machine that is set up with a printer, the command is usually "`LPR`" which stands for line printer. Some machines have a better print program called `PRINT`.

So you type `LPR space file name` or `PRINT space file name` and it will print the information. However, if you're dialing in from Boston and you're talking to a computer in California and you type "`PRINT`," hopefully the system administrator has set it up so this won't work, but if not, you could end up printing stuff in the computer several thousand miles away. It doesn't know where you are, but you're logged in. If you have the permissions you have the permissions, so it won't necessarily print on your printer. It will print on the printer that is connected to the UNIX system. You can print. And that's a function really of your terminal program.

For instance, the Telnet program that I'm using has a capture function as do some for Windows. But if you're sitting in the home terminal or something, you may not be able to print at all if it doesn't have a printer attached to your machine.

M: [inaudible]

Kevin Savetz: `PING`. `PING` is a program... actually, Ping is an Internet protocol and it is also a program on UNIX. One of those rare cases that the thing is actually named correctly for what it does. Ping lets you find out if another computer on the Internet is alive, is awake and actually

on the Network right now. So if you type PING redwood.northcoast.com it will say, "Hey redwood. Are you out there? Do you exist?" And if so, it will say, "redwood is alive." And that's all you need to know. Also, on many implementations of UNIX if you type "PING -S," it will tell you exactly how many milliseconds it's taking for packets to get to redwood and come back. So you can find out, "hey, do I have a fast connection or do I have a slow connection?"

M: [inaudible]

Kevin Savetz: Right, so it's very, very useful. For instance, if you're on a system and you're trying to tell it [inaudible] and it's not working, trying FTP and it's not working, you might try pinging your router or the next machine in the line. "PING-S whatever it's called," and it will either — I think it tries for a while and then it says, "redwood is not alive," or something like that. It basically will think about it for awhile and say, couldn't get there.

W: But how do you know [inaudible], how would you know that?

M: Is there anything that tells a browser [inaudible]?

Kevin Savetz: Basically, in answer to your question, you might ask your system administrator, what is our router called? And that way you can do some basic troubleshooting yourself. Because if you can't get to the router, then there's a problem and you're not on the Network because the router isn't. There's a separate program called TRACE ROUTE which is not default on all UNIX systems, but if it's there, that's what it will be called. And if you type TRACE ROUTE redwood@northcoast.com, it will tell you every machine between you and the destination. And it's kind of cool.

If you're here in Boston and you type "TRACE ROUTE," there might be five or twenty or more machines. And it will give you the names of them and you can look and they'll have these really cryptic names so you can go, "Hey, my packet is leaving Meckler and it's hitting ANS and then it's going on to SprintNet and then it's traveling through a bunch of routers and it's reaching its destination." And if you try to trace route and it doesn't do anything, then you've lost your Internet connectivity. Also, it's kind of a good way if you want to seem like a smart guy to your system administrator, you can say, "My packets are getting as far as SprintNet, but not any farther. Fix the problem."

M: It tells you when it stops.

Kevin Savetz: Yeah. Well, it tells you the last machine it can successfully get and, of course, the Internet is pretty robust. If there's a way around, it'll try to find it. But sometimes a key machine is down and it just can't get there, so... Other Internet tools, there's PING, there's TRACE ROUTE, there's FINGER. We talked about MAIL. We talked about FTP, also TELNET. Basically, you type TELNET space the place you want to Telnet to and it does the basic Telnet protocol interface type of thing. It's fairly simple. I think those are the big ones. Any more questions at this point?

M: [inaudible]

Kevin Savetz: I'll talk about those in a minute. I'll touch on them. After CAT, which will basically dump stuff to your screen and in my little demonstration, I would CAT a long file in it with a scroll away... not very useful for long information, so there's a program called MORE which is

basically just like on DOS. You can PIPE something to MORE and it will give you a screenfull and say "More" at the bottom of the screen. If you want more, you hit the space bar and it will give you another page. Actually, there's two ways to use More.

You can just ask "Is this a file name?" with a file that you just want to look at. You can type More file name and it'll do that. Or you can take the output of anything and PIPE it to MORE. So, basically, you can run a program that will tell you the last 300 people to log into the system, or you might just be rerunning a database program that's going to run for a while and give you a lot of output, and you just want to look at it a page at a time, so you PIPE it to MORE and then it will just give it to you a page at a time. That's standard on all UNIX systems.

Some UNIX systems have a program called LESS, which does the same thing as MORE, only better. And as they say, LESS is MORE. Not necessarily on all systems, but it's a little bit more functional, a bit nicer, and if you've got it, use it.

Shell scripts are collections of commands, basically collections of UNIX commands that you put into a file, make that file executable because it's really a simple program and then when you run the program, it'll do all the commands that you want in order. So, in its simplest form... for instance, there's a shell script for every user in your home directory, a hidden file called dot login. And when you log in, it runs the shell script which basically it does things that we saw when we logged in. It shows you the message of the day, it asks you your terminal type, sets some permissions on things and does some basic... it's basically a collection of commands to run. There are different types of shells. We have been using a shell called the "CSH" which is a fairly standard and that's written out as CSH, but is pronounced "seashell."

If you've used DOS, you're familiar with command.com which is the basic shell, but you may also have used something called ForDOS, which is a replacement shell for DOS and it has all sorts of funky things, where if you hit the "up" arrow it will page through the last few commands that you've typed. You can type... it has a bunch of extra functions that aren't in the normal shell.

Well, in UNIX, there are probably about ten different shells that you can use. The standard basic one is called the "Bourne Shell" and that is just written out as "SH." Just shell. And then there's the "C-shell" and there's the "T-shell" and there's the "Bourne Again Shell" and there are a bunch of different shells and frankly, I'd just use whatever you are given unless it seems really under-powered to you. Shells might let you get a history of the last 50 commands that you typed, and if you just entered a very long command, you could say, "Okay, do the command I did eight commands ago. Just do it again. I don't want to have to type it." Some shells let you have aliasing. It's very common.

If you type LS-CF a lot, you can just change that so it's LS [inaudible]. So you can save some keystrokes there, save typos if you always type CTA instead of CAT... whatever. You can do aliasing and very simple or very complicated aliases. So, some different UNIX systems have many different shells installed and you're probably given one by default and if you want to change it, there's usually a command called "CHSH" which means "change shell" and then you can change between the different shells in the system. Basically, it's just an interface thing. It only has to deal with you. People can have different shells. It doesn't matter which one you use really except for what you prefer.

M: [inaudible]

Kevin Savetz: Yeah, there is a command... The question was how do you find out what shell you are using? There is a command called "PS" which means "process status," and basically this is a command that will tell you what programs you are currently running. Since this is a multi-user interface, you could be logged in for multiple places, a bunch of different terminals, or maybe

you walked away from a terminal and forgot to log out. If you typed PS, it will list everything that you're doing.

[Tape change]

Kevin Savetz: ...whether you're running, you can just look at the column there and see whether you're running C-shell or Shell or the Cornshell or whatever.

W: [inaudible]

Kevin Savetz: On most systems, if there are multiple shells, you as the user can change your shell by typing CHSH.

M: You could learn a special set of commands [inaudible].

Kevin Savetz: Yes, aside from the UNIX commands, there are a special set of commands just for your shell. O'Reilly & Associates publishes a whole bunch of books. O'Reilly publishes a bunch of different UNIX books and if you want to learn the intricate details of the C-shell, you can get a book just on the C-shell or the Cornshell or whatever. But for the real basics of UNIX, just type the commands. You don't have to worry about the real details of the shell. There's a question back here?

M: [inaudible]

Kevin Savetz: Your operating system, like on the Mac, the UNIX is the OS, but the Finder on the Macintosh or Windows is your shell. But, unlike on the Mac, you can change your shell if you don't like it. That's powerful. Speaking of change shell, there's another one called "CHFN" which is "change finger name." As I said, when you Finger someone, you can find out what their name is. What their real name is and [if], for some reason, you don't want the world knowing who you are, some UNIX systems have CHFN, so you can change your name, just have your last name, for instance, if you wanted to.

Also, you may be able, with CHFN, to put your office phone number so people won't have to call you via other means rather than sending e-mail, although I don't know why anyone would want to do that. You can put other information about yourself using the chfn command. One of the things I was going to demonstrate, but it's just not going to work was setting up a very simple Web site on a site that already had a Web server.

Some Internet service... Just to kind of put some of these ideas together, some Internet service providers such as North Coast Internet have a Web server and they let users create their own personal Web space. And the way they do that is they tell you, "well, you have to have a directory call www." Sometimes it's called "public_Web" or something like that. And anything that you put in that directory will be available on the WorldWide Web and it's a nice little way for people to say, "Hi, I'm Kevin. Here's my Web page."

Now that you have learned that as well as a couple of others that I'd like to touch on, we're going to pretend we have some UNIX that are connected and so... on North Coast Internet, for instance, and as I said, this is fairly common, you need to have a directory called www and so we're going to make a directory under our home directory called www, and that's where all of our Web files are going to go.

Since these files are going to be readable by people all over the world, this directory and its contents needs to be world-readable and world-executable. So, we're going to create the

directory and then we're going to type CHMOD A + RX www. So now we have a directory. It's readable. This is where our little work of art is going to go. And then, CD worldwide web, www.

So now we're going to move into that directory. If you type "LS-l", you're going to see that there's nothing in there yet. Now we want to create a home page. And it's going to be called "welcome.html." A couple of ways to do this: you can use the VI or the EMACS or the PICO editor to go in there and create it, or something that a lot of people prefer to do is you can use your PC or Macintosh to create the information and then upload it to the UNIX system. You might be more comfortable with Microsoft Word or you might have a big graphic that you've created in Pagemaker, I'm sorry, in PhotoShop. So we want to upload some information to the system.

Basically, you can use whatever tools you're familiar with. Make sure that any text is in text format because UNIX won't understand a Microsoft Word document, for instance. And then you're going to FTP it from your machine to the host computer. That involves firing up FTP on your machine and then logging in with FTP.

Now, since you have an account on this UNIX machine you're not going to be using anonymous FTP, and 99% of the time, if you have FTP, you don't have an account on that system so you're using anonymous. But since we have an account on this machine, rather than logging in as anonymous, we're going to log in as Hootie or whatever a login name is. We're going to use our password and you're going to find yourself in your home directory under your FTP [inaudible]. You're going to change into the FTP directory and then you're going to put the files that you want to put.

So we use our FTP tool to upload a HTML file called "welcome.html" and, of course, only ".htm" if you're using Windows because [characteristic of] DOS, you only get three letter extensions, that's okay. And we're uploading picture.gif. So they're now on the UNIX system. Is there a question?

We quit our FTP client. We go back into Telnet, so we got the information there. I've found that on many FTP clients, when you upload information, it gets the permissions really funky. On Macintosh, the two programs I use a lot, Fetch and [inaudible], they leave everything world-writeable, so any idiot can go in there and start messing with your information. So, that's bad. So now we've uploaded our stuff on the www directory.

M: [inaudible]

Kevin Savetz: Yeah, I think you can. [Inaudible] just came out and it's still in beta and I haven't played with it a lot, so you upload your goodies and then we're still in the Web directory so we can "CHMOD OG-W*". Okay? So, now it's not world-writeable. Everything that's in there is now writeable by the user and just to make sure that everything is readable, we can "CHMOD A+R*". So, we've made sure that everything is readable, but is not writeable. And now you type "LS-l" and you'll see that you have two files there: "welcome.html" and "picture.gif."

Uploading from DOS machines is interesting because DOS originally had three character extensions and also DOS machines don't differentiate between upper and lower case. So you may want to rename your file from WELCOME (all the capitals) dot htm to MV, use the MV command to rename it to be welcome (lower case) dot html. If you want to. There's no need to. You can leave it dot htm if you prefer, but UNIX is case-sensitive, so if you're pointing to picture dot gif all in lower case and it got... when you uploaded it, it got uploaded as all capitals PICTURE.GIF, it's not going to be a valid link because capitals and lower case matter.

So that's pretty much it. You CHMOD it. You make sure that the file names have capitalization that you want and it should be on the Net and in many cases, on most systems

that I've seen it's done with and this is not a hard and fast rule, the URL is the name of the site and then a "tilde," [~] the user name and then the file name. This is just for public access UNIX. So in this case <http://www.northcoast.com/~hootie/welcome.HTML>, which is "welcome.HTML."

M: What does the [inaudible] do? It automatically sends you to...

Kevin Savetz: The tilde [~] basically tells it that this is a user directory. It's not something that the system administrator set up. It's not in the main directories for HTML. It's off somewhere else, so. And it also kind of guarantees that in this instance that people out in the world can't get into stuff in your home directory. They can't go through your files. They can only get into stuff in your www directory, which kind of protects you a little bit. Yes?

M: [inaudible]

Kevin Savetz: Nope. No reason to have HTML on your files at all. If you cruise the Web, you're going to find that 90% of the Web pages are going to have dot html extensions, but it's convention. Other than that, there's no reason for you to do it. You can have no extensions if you want. The UNIX machine doesn't care. It will serve the information either way.

M: I'm sorry. I just sort of missed that [inaudible]. That is put in by the system administrator [inaudible].

Kevin Savetz: If the system administrator has set things up so that any user can create a Web page, the general convention is that the URL for that is the name of the machine and then tilde, the user name slash. And that just basically says this is a user Web page. The tilde generally means home directory.

M: Okay. And you can't [inaudible].

Kevin Savetz: It depends on the system, but usually no. But then again, if you're the system administrator you can set things up any way you want and you don't have to deal with the tilde at all. If you are the system administrator, then there's generally a place called the root HTML directory which is where everything else goes. Things [inaudible] especially user accounts. So if you have an on-line shop, you would say, "well, the root directory of this on-line Web store is on the UNIX system in slash/user/web" and everything under there is basically the Web directory that you have set up yourself. Okay? Yeah.

W: I don't quite understand [inaudible] you don't need an HTML tag, but say for example, you're using Windows and you're creating a Web document maybe like in [inaudible] and then I want to ask you [inaudible].

Kevin Savetz: No, you don't. The question is if you've created it on Windows with "name.htm", after you "P" it up to the UNIX system, it's still going to be named that HTML, you don't have to rename it.

W: [inaudible]

Kevin Savetz: UNIX itself doesn't require the naming. The Web server in question may require things to be HTML. I hadn't thought of that. So, yeah, on your system, I suppose that was the

case, it requires... it needs to have the HTML, but in this case it's the Web server that's requiring it, not the UNIX system itself.

M: [inaudible]

Kevin Savetz: Right. On some Web servers. Right. That's why I use that name because [inaudible] on many servers. Any more questions at this point? I'm open to going off in a minute. My canned spiel is pretty much done so I can go anywhere at this point.

M: [inaudible]

Kevin Savetz: If you tried to look at a GIF or anything that's not text [inaudible], for instance you've got CAT picture .gif, your screen is going to fill with garbage. It would be like taking a GIF file and feeding it to Microsoft Word or any word processor. You're just going to get garbage.

A way to find out what type of file it is, if the extension isn't helpful, the last [inaudible] you can type "FILE file name" and it will try to figure out a little bit about the file. It will say file name is [inaudible] text or file name is an executable program or it will look at the file and try to figure out what it is for you. You might not be able to say, hey, this is a GIF file, but it can say, this is data, you know. So you'll know not to type CAT file and [get] garbage all through your screen. Yes sir.

M: Do you have a user menu [inaudible]

Kevin Savetz: You have a menu on your system and you want to change what's on it and you don't know what it's called. Start searching. Just kind of look around. If you use the user menu, you probably run a command to bring that menu up... maybe? No? I don't know.

M: Well, actually, we log in [inaudible].

Kevin Savetz: When he logs into a system, it automatically comes up with a menu instead of the UNIX interface and that means that under your account, probably in the dot login file in your account, it says instead of running the shell, we're going to run a particular program. And honestly, it depends entirely on your system, how it's set up as to if you can change that menu at all or if you can avoid using the menuing system at all, it really depends on how your system administrator set things up. If it set it up to be real secure, then you can't avoid it and you can't change it. But it may not be.

M: [inaudible]

Kevin Savetz: Yeah, probably a default login file. The other thing that the system administrator could do is set your default shell instead of being C-shell to actually be the program, be the menuing system, so... and that's something that the system administrator sets in the password file or if you can get to the chsh, the change shell command, you may be able to change that.

M: How many commands [inaudible]

Kevin Savetz: Oh, probably... I don't know, 15 or something.

M: Can you survive with that or how many [inaudible]

Kevin Savetz: Well, so far we can... assuming you learned your editor yourself, you can create a file, you can delete it and rename it and move directories around. You can create a Web page. So, at this point, and you can even search through files for certain information, so at this point that's a good portion of the UNIX basics. Once you know how to have a mail program installed, you can do some of those slightly more moderate things you can do as well. So this is really, you can get around... and, of course, you're going to sit down and use the machine and the first thing you're going to do is going to be something that we haven't talked about.

But as far as basic file manipulation, directory manipulation, those are the big commands. And if you want to know more about a particular command, you type man file name and it will tell you about that command and also about related commands as well. And again, very soon, the bibliography that I gave you, the URL, will be on-line so you can get more information from this book. Yes.

M: So with the Web pages [inaudible]

Kevin Savetz: For Web pages, they basically need to be world-readable, that's a plus r. Because basically, a person out in Finland looking at your Web page, he's out there. He's no one to the system so it has to be world-readable. For any Web directories, that is directories with HTML code in them, those have to be readable and executable.

M: [inaudible]

Kevin Savetz: The directories have to be executable because the people are going to be looking in them. They are basically looking for files in them.

M: What's the difference between executable and readable?

Kevin Savetz: As far as a file goes, if a file is readable, that means you can look at the contents of it, but not run it if it was a program. An executable... for instance, a shell script or a PERL script needs to be executable if you want to be able to run it. If a directory is executable, that means people can look inside of it.

M: Oh, I see. Versus if the directory is readable...

Kevin Savetz: Now I'm confused. Just make them executable and readable. I'm sorry. It's been a long day. If it is executable, then people will be able to run programs inside of it. If it's readable, then people will see the content of it, I think.

M: Hypothetical. Suppose you wanted to set up a UNIX machine in your den to play with it.

Kevin Savetz: You're a sadist. Rather, you're a masochist and you've set up your own UNIX machine in your den. Okay.

M: What sort of minimum configuration is required?

Kevin Savetz: What sort of minimum configuration is required? It depends on the type of UNIX that you're running. For instance, [LYNX] which is a freeware, completely public domain

version of UNIX requires — and which is very good, by the way — it requires a 386 with eight megabytes of memory. So, not an overly-powerful machine. And basically a CGA monitor is enough because you're just doing text. [LYNX] is something that we haven't talked about and I don't really, honestly don't know very much about it. Some versions of UNIX has something called X-Windows which is a graphical interface to UNIX which is a whole lot like using Windows or using a Macintosh, with the mouse pointer and the buttons and the clicker and things you click on and everything.

And if you want to use X-Windows as well, that will probably require a VGA monitor and probably some more memory, 12 megs to move all that information around. There are a couple of versions for UNIX for the Macintosh, although I don't know what you'd want to do that to your Mac. One is called Mac-10 and that's commercial software, \$500 or something like that, and there's another one that's a Mac version of [LYNX] which is just coming out and is in beta testing, I believe, at this point. Other versions of UNIX, there are [inaudible] if you have a Sun sitting in your den, or Solaris also for Suns.

But basically, for hobbyists, use probably [LYNX] as the way to go, and that's free. There are some versions of [LYNX] which cost as much as \$50 which are like on CD-ROM and they're ready to go with a lot of documentation, so sometimes... you can get it for free, but if you pay a little bit of money for it, you can get some documentation and have it a little bit easier to use.

M: [inaudible]

Kevin Savetz: Yeah, I think you can set up a partitioning so that when you boot the computer, it'll say, "okay, do you want to be UNIX or do you want to run Windows?" or whatever.

M: [inaudible]

Kevin Savetz: Oh, good question. Setting up a UNIX machine in your den... is it a Web server? Assuming you set up [LYNX] for instance, and then you have an Internet connection, you've downloaded your Web server, you've installed it and many of the major Web servers such as [inaudible] hypertext demon right under [LYNX], yes, you have a Web server.

However, do you have a full-time Internet connection — if you have a Web server, as you probably know, it needs to be on-line on the Internet 24 hours a day, so... and a 28.8 modem is not going to, even if you're logged in all the time, isn't going to cut it if you have a popular Web site. So basically, if you have 128K or ISDN or T-1 going into your living room, talk to me if you do. But basically, yes. The answer is yes. You have a Web server, but assuming you have a decent Internet connection to actually serve the Web.

M: [inaudible]

Kevin Savetz: In your Web server software. Web server software is generally called an HTTP demon or HTTPD. There are several different types of those available. You can get them for free. I've used a couple of them. One is called the CERN HTTPD and it's a nice, basic free one. Pretty easy to set up, does the job.

If you want to do commercial transactions, want to take people's credit cards and that sort of thing, the only reasonable choice that I know of today is Netscape. The Netscape commerce server is \$5,000, but then you can do all that good encryption so that you can get private information relatively secure that no one's going to be able to grab that information from you.

M: Is it fairly easy to install? What kind of installation costs?

Kevin Savetz: Netscape, actually their server is fairly easy. They have a whole installation of forms, many basic installation thing. It's pretty easy to use. Pretty easy to set up. Yeah.

M: [inaudible]

Kevin Savetz: I could get into trouble for... if I say something then somebody, somewhere, will disagree with me.

M: [inaudible]

Kevin Savetz: Honestly, I've heard great things about some Windows NT Web servers, so I mean... if all you want to do is set up a Web server and you have no vested interest in UNIX and this doesn't need to be 20 people setting up their own Web sites, if there are just one or two people in control of the thing, you can use Windows NT and avoid the whole UNIX thing altogether or you can use MacWeb and do it on a Macintosh. There is not necessarily a marriage between UNIX and Web servers, although Web servers for UNIX are very robust and can handle many people at once.

As for whether a UNIX Web server will handle more simultaneous users looking at your Web page, not necessarily. If you have a 286 running [LYNX] versus a Macintosh with 128 megabytes, the Mac will... basically, it depends on the system itself. There's no necessarily right or wrong way to set up a Web server. You had a question?

W: Say, for example, you have like a Home Page up right now and you have an Internet provider [inaudible] and so you're thinking you want to go out and buy your own server. What do you need?

Kevin Savetz: You need a host computer, whether it's UNIX or whatever. The question is, you want to set up your own server, what do you need? You need a computer, a full time Internet connection and basically, you need one that's relatively fast even if it's going to be... I wouldn't go slower than ISDN. And the cost of ISDN depends on where you are. In California, ISDN is usage-based, so if you're logged in to ISDN all the time then you're going to get a pretty hefty bill anyhow. So, you have an Internet connection, an ISDN or T-1 or whatever it is. You have an Internet service provider. You have to get your Internet connection from somewhere. And you need your Web server software that you can set up on your system. These are the four basic things that you need to set up your own Web server.

W: [inaudible]

Kevin Savetz: Can your computer do other things? Depending on the load on your Web server and what you're doing to it. You may be able to share... I mean, certainly, if you have a UNIX machine as a Web server, you can log in and send e-mail and do other things while it's serving Web. Assuming you have enough memory, you can use Microsoft Word or crunch numbers in your spreadsheet while your Web server is going on. Now, of course, hey, if you're running a program that crashes your system, then you'll probably just crash your Web server as well. But if you want to go on the cheap, you can use a computer to do multiple things.

W: Well, I mean, ballpark figure.

Kevin Savetz: Ballpark price. It really depends on your specific set-up. I would say for the first year, guessing, this is the ability to fluctuate... \$10,000.

W: [inaudible]

Kevin Savetz: A firewall would be a totally separate thing, yeah. Was there a question over here?

M: I was just going to ask you about the security issues.

Kevin Savetz: Well, yeah. It depends on your system and on what you're doing. The question is about firewalls. If you have a machine in your den or whatever, and it's only a Web server and you don't have a network at home, really you don't need a firewall because the Web... the nature of your Web server is you want people to be able to use that information and there's no connections to anything that people could hurt, so you don't really need a firewall.

Now, if you have a UNIX system that you are using as a Web server and you have your profit and loss statements for your business and a lot of other important things, then you need to have a secure system and possibly a firewall. Firewalls are very expensive, however, and there's many, many different options. You can go out on the show floor and say, "who's got a firewall" and twenty people will run up to you from different companies. You can get hardware ones and software ones. They tend to be very expensive and pretty complicated. I honestly don't know a whole lot about them, but if you are worried about people getting access to your information, then you can either put it on a separate network so people physically can't get there or you can set up a firewall.

TUTORIALS HOTJAVA, MULTIMEDIA AND THE WEB

SPEAKERS

David Levine
President, HuskyLabs
Matt Davis
HuskyLabs

David Levine: How many people here run a Web site? Great. Okay, how many here don't? Don't be embarrassed or anything. How many people do their own HTML? Great. How many people do their own graphics? How many people do their graphics well? How many people incorporate other forms of media like audio, video clips, that kind of thing? Okay, great. It's pretty sophisticated.

How many people have programmed in C or C++? Wow, okay. How many compile programs that work? Anyone familiar with PERL? Great. So this is pretty sophisticated. For about half the audience, we will try to keep things pretty simple and try to explain things clearly. If you have any questions at any point, definitely just raise your hand or shout or argue or whatever because it's a long tutorial where you don't have computers and actually get to try things yourself, so we're going to try to make sure you get as involved as possible.

There are really two aspects of this that we're going to be covering. One is using Java, which I'm mostly going to be focusing on; and one is writing your own applications, which is what Matt will be focusing on. So we'll start with more of the background and why Java is important and what it is and those kinds of things. If I get my facts wrong, it's just because I don't work for Sun — he doesn't work for Sun either — and this is all stuff we've picked up on the Net and tried out and learned ourselves and that kind of thing.

So we're very much coming at this as a Webmasters also, who recognized a new tool and decided this would be something really good for us that we're going to get into.

Basically, we've spent the last week and a half trying to get Java to run within Netscape . Very recently, Netscape licensed Java and said they were going to incorporate it into their browser. And in about three weeks of all-night sessions, the folks from Netscape and the folks from Sun got together and sort of kluged it together and made it work a little bit, and in the process broke everything. So we're in the process of moving from an alpha code to a beta code. It really wasn't a trivial upgrade, so if you're just starting now that's actually good because you'll get to start with a beta code and then they'll only have problems when they get into the production code.

What is Java ? First, we'll talk about why we consider it important and what the Web is right now and what it will be post-Java. Basically, the Web as it is right now is a bunch of files, just separate files all over the place, where you have one central language — HyperText Markup Language — kind of binding the thing together. What's on all these servers out there are various audio formats, video formats, graphic formats, some of which the browser developers have been able to incorporate actually within the browser but most of which require other applications. When you're doing your Web sites and you're doing audio, how many people use primarily .WAV files? How many use [QuickTime] files? How many use "Reel Audio"? Is there anyone out there who can tell why they made whatever decision they made in terms of what file format they decided to use?

M: [inaudible]

David Levine: So you're developing an internal Web for your organization? That's a real good example. He knows his audience and so he has picked a file format, probably the AU format I believe is what [inaudible] kind of thing. That's what the Mac sound player plays, so he's prepared all his files in that particular thing and he's relying on the fact that they have a helper application so that when they download that file it's going to launch automatically.

They've configured their *Netscape* right where it knows what helper application to look for and all that. Now, if he were at a very public site with a wide range of audience, he would have to come up with three or four different file formats to make sure everyone could listen to the same file. Even then they might have things configured right. He might have to put pointers to all these various helper applications out there around the Web and it's a big kluge because it's a pain in the neck to not know if your whole audience out there is going to be able to use the whole site that you've set up.

Another problem is download time on those files. You want it to sound good, and the better you get it to sound, the bigger the files get. Then people have started using Reel Audio [inaudible], which do better in that they compress the files a lot and stream them over the Internet. But, again, the helper applications aren't on all platforms, they're not easy to configure, so right now we have all these problems that the Web has introduced.

You have a company, Netscape, that said, we know how to fix all these problems. We'll write plug-ins for everything out there and if anyone develops their own system — like Macromedia *Director* has Lingo as a programming language, or scripting language, they have a self-playing projector thing — we'll make plug-ins, where anyone who develops a new medium can then write a plug-in. We'll incorporate the plug-in either into the *Netscape* if we think it's really important, or we'll provide an easy way for you to give us... we'll give you the code for *Netscape* as a developer in order to develop a plug-in.

Then we'll put it on the site and somehow this will be better for everybody because it will be more administration and delays and all that, but somehow people thought that would solve everything. It kind of made sense. There are companies out there like Zing and Reel Audio and you say, okay, well if Netscape is going to incorporate them, then I can produce Zing files and Reel Audio files and whatever other proprietary things I want to do and at least know I'm hitting a good chunk of the people out there.

Well, it sounded pretty good and people were real excited about the fact that their *Director* files would be able to be viewed over the Web. You'd have a nice new distribution mechanism. But it was real obvious that as soon as Sun introduced the concept of the Java programming language that there was going to be a real shift and Netscape jumped on it real quickly and now Oracle's jumped on it. The real forward-thinking companies have seen something new and this is basically what they saw. They saw something that really wasn't multimedia anymore; it was a single medium and that medium is Java.

[Arthur van Hoff], who is an engineer at Sun, wrote a browser from the ground up in the Java programming language, which is called HotJava. What Java does is, basically, allow you to write with whatever you want people to get. You still program in it, you still mark things up in HTML, you still produce files of whatever format or type you want; but with those files you send small bits of pre-compiled code along with those files and along with your Hypertext to the browser, HotJava. When it arrives you have your players there, you have all the tools you need for someone to experience what the designers and the programmers and the writers and everyone else has conceived. So all of a sudden you have infinite control over what you want people to see and how you want them to experience it.

Other tools we are seeing coming up more and more — terminal log-in programs so that someone can actually, within the browser, have a chat window and communicate with other people. Shared whiteboard space. We're going to show a lot of those things and talk to

you a little bit about how they work. Basically anything you can write in C or C++ and compile, you can write in Java and send it along.

The way I'd like to look at this, as an overview, is that now you just think about the medium; and a lot of people have been asking me, well, it is still the Web with Java if its people can invent their own protocols, they don't necessarily have to rely on HyperText Transfer Protocol. Once you get the stuff you can write any protocol you want and talk between the browser and any other servers and you have networking built in.

How many people have used CGI a lot — the common gateway interface? I figured. It's really the only way to get stuff done. You probably use it for search engines. If you have a big site with a lot of documents, you would have someone basically have a flat form, fill out the form requesting particular documents, send it to the common gateway interface, where you would have a script or a bit of compiled C code to then do the work and send the document back that would be displayed.

Pretty much everything you're doing on your site that's at all complicated, like image maps — you basically have your graphic and within the map you'll outline certain objects, drawings, whatever it is, click on that, it sends a couple packets to the server, goes into CGI, where it finds the map file and says, "okay, he clicked on that particular coordinate. Okay, that coordinate links to this file. Send back that file."

Again, all the work is done by the server. All one had to do was just record where the mouse click was and send that information. What you're going to be seeing more and more are dynamic image maps because, again, Java is able to harness the user's computer, the client's computer. When you get a new image map, a "Java-tized" image map, there is actually a little bit of code that comes along and says, when my mouse moves over this coordinate, right then and there pop up this menu; or release this audio or change this image to do this.

So before the guy even has to send something back and get a response, you have a media interactivity and that's much more gratifying for a user. We'll talk about particular applications of that.

One of the main shifts between the way the Web works now and the Web post-Java works is that you're harnessing the processing power of the host computer and you're really distributing the functionality of your programs.

So, what is Java like and how is it like PERL, how is it like C and those things? Basically, it has characteristics of all of them. It is interpretive — you need a Java interpreter. You do pre-compile it, but there's a run-time component that checks everything out on the client. And in Netscape and on HotJava you basically interpret what the language is. What they're talking about is doing a more fully compiled version that will actually get you the same speed as C and C++. That's the one between Java and C and C++, basically, because there's a run-time component, it's not quite as fast.

You've all probably heard a lot about *BlackBird*. I have no idea what it is except for what I've read and everyone says this is going to be the main competitor to Java. A real big difference I imagine... how many people have heard of *BlackBird*. and know what it is? For those who don't, it's a publishing system that Microsoft has developed which they say will provide interactivity to the Web using OLE, Object Linking and Embedding functionality.

You can link all your different applications and on your desktop to Web documents and things will come in and go right into Excel and do all these things that people have been talking about. What Sun is saying about this is that if you're using Visual Basic, basically, it's totally insecure. It would be so trivial to write a virus and send it with that.

The reason they're claiming that Java is secure is that when things are compiled they're all checked for anything that is nonstandard. It only allows you to do certain things when you compile it. If anyone has tampered with the compiler, then the run-time checker will see, okay,

this hasn't been compiled according to all these rules so it's not going to work. All the legions of C and C++ developers who think, wow, this is a way to distribute my code using *BlackBird*... I think there will be a lot of fear out there. There is also not multi-platform support. There are some of us who use UNIX and don't get to see things that other people say, oh, it's like this — like Reel Audio, I've never listened to that.

Magic Cap is another kind of vaporware-like thing. As far as I can tell, I used to live next door to the brother of the main developer and he would give me all these great releases and technical specifications and stuff, but who knows exactly what it is and how it's going to work. They talk about intelligent agents, little agents that go out into the Internet and find things and make reservations for you and all that — well, Java gives you those capabilities.

There is one project I can't really talk about, but there's a government agency who's looking at using Java as a way to really do their legwork where they don't have to... you know, they write agents in Java that'll go out and find things and collect information or whatever and come back. Java would be a very good language to do that in.

How many people have built worlds in VRML? One?

M: [inaudible]

David Levine: You've implemented them on your site? What were they like? What were they for?

M: [inaudible]

David Levine: What he said, for those who couldn't hear, is in *3-D Studio* he built a store where you can navigate through the store and find objects or fly through it. He had the light so it would change so that you would get the sense of actually being within that store.

Just to digress a little because a lot of people haven't been following VRML and what it is. It stands for Virtual Reality Markup Language and it was introduced about a year and a half ago at the CERN WorldWide Web Conference as a way... the guy who wrote it, [Mark Pesci,] was actually thinking — what he was trying to propose was a specification called the cyberspace protocol, where you would get seamless movement between Web sites. He had this idea that it would be `cs://whatever` if you were going to be using the cyberspace protocol rather than HTTP; he saw “get” and “post” as the only things you could really do. You can't provide boundaries and those kinds of things.

But people pretty much ignored the cyberspace part and looked at the markup language and said, “That's kind of neat. We can create a static space we can wander through, pick objects, click on them and then access a URL or access another world or access a medium.” There was a list running off of... that the guys at *Wired* set up, where people were discussing VRML and what to do with it and the specifications for it.

This is kind of an interesting business lesson. Mark, basically, when he first wrote the first browser called [inaudible], he did it using *Rendermorphic*. He used their rendering library for the PC, so you could navigate through this world and all that; but he hadn't really worked out the licenses or anything, so he couldn't distribute the browser for free and all that stuff.

All of a sudden Silicon Graphics was participating and said, “We'll give you “Open Inventor” status and we'll use this as a text-interpreted world so that you can do all the markup and things you want to do.” At that point Silicon Graphics sort of took it over. It basically is Open Inventor and you create these worlds and you can wander through them, but there is no activity, they're just static. I kind of lost interest at the point where it just kind of became very defined and slow-moving

But one of the problems I found [was that] there were infinite arguments over the Internet about how you would define particular objects within VRML, like how would you define a chair so that everyone wouldn't have to redefine a chair every time — if you just sort of take that chair and add your own textures, add your own cushions, all that stuff. Finally, someone asked, "Why would you want a chair in cyberspace? You don't actually have to sit down."

One thing I realized is that all that stuff from the real world, like lighting and shading and all this stuff, kind of gets in the way, in a lot of ways, of actually understanding something. What we pay attention to as programmers and developers and scholars and all those things, actually what is most important in this room in a lot of ways is the text, is the flat paper. Text in a lot of ways is virtual reality when you get into it.

I started seeing more and more VRML, even though you could create new worlds that didn't exist in this one, it had new features. What you were dealing with was space and light and things that in a sense took away from communication.

Where this is going is that with Java you have a modeler that incorporates things like PostScript, which shows font definition and all that, but also incorporates things like [inaudible] and incorporates any computer concept. You could model a world with Java and then that world can just change into a book. And it's much more. Rather than spending all the time defining all these things that 3-D graphics people are very interested in, the time with Java is spent at the very low level of actually deciding what you want all these things to do.

When Matt gets into object-oriented programming a little bit and talks about defining behaviors and methods and those kinds of things, you'll see that this is a tool for building rather than defining. We have a chair and we have a table and we've all defined what those chairs and tables are like — now we can start building our world.

What Java does is we have something that plays a sound and we have something that knows when your mouse is over a particular space and we have this object over here that knows how a particular wheel spins — those behaviors you can then start to use. You could build real worlds and real programs with these various objects that other people have already developed.

It's going to become very interesting to see who is giving away their software, who's trying to sell it, who's giving away source code. It's really going to change the software industry, and the main way that's going to happen is by taking away the API from Microsoft. Right now people develop for Windows because that's where the money is and you can't sell an application that doesn't at least have some Windows component or else you sell it for a lot of money and a few people buy it and you can do okay that way.

Just the fact that Gates controls that API got him \$50 billion or whatever he's worth now. And because people basically have to develop for his operating systems, all of a sudden there are all these applications that are run on his operating systems. Okay, so we need to buy his operating system and then, okay, will those work with all these other Microsoft products... we have to buy all those products and all that.

What you're going to see happening is when people write in Java, they're not going to care anymore if you're running a Mac or if you're running a PC or if you're running whatever. If I write an application in Java and I want it to do one particular small thing like create a shopping cart with a spreadsheet attached, so whenever someone puts something in the shopping cart and the spreadsheet is updated a little bill is there, and someone takes it out.

We want that all to run on the other person's computer, so it's actually dynamic and happening in real time. That little applet I could give away free; it's easy because I'm getting someone to actually shop in my store. Or if the service is an information service where I want someone to be actually doing math or getting stock quotes or whatever, I can just charge for

the use of that applet for a particular period of time, the use of that small application. I could charge the billing mechanism into the applet and I can build all the user information into that applet.

There is all of a sudden a tremendous amount of ability that's being given to the programmer that is not controlled by another company. I don't have to worry about the things that come up, like moving from HotJava to Netscape — I mean, those kinds of nightmares where they just break everything at once, but they apologized and said no we're not going to do it again and this is a frozen API and all that stuff.

Sun has, in terms of licensing, given away the right to use the language, to develop tools in it and you have to read through all the licensing stuff in terms of what that means in terms of selling stand-alone applications and selling them. I'm really not sure how that works. I'm not a lawyer, so, you don't have to do stuff, you just call the lawyer and say, does this make sense.

It is much more open. In a typical Sun Microsystems way they've really made it an open specification, so, for example, anyone can [inaudible] the application to whatever platform they want and really do whatever you want with it over the Internet. Imagine if you're going to develop something in Java that only runs on Windows NT and sell that as a stand-alone application.

Or like what Netscape did. They licensed Java and I'm sure paid some money to license its incorporation into a commercial product. You have to do that, but you use the language for all these other things that run over the Internet. You're not going to have to pay them anything, which is good. Probably at some point they're going to be coming out with their development kits that are going to help author things, so they're probably hoping to make money on that kind of stuff.

One thing with the Java browser and Netscape, it really supports innovation. If you write a new program and send it out, it's not going to break anything. If it runs and works, you've innovated without actually making people upgrade to support that new thing. You don't have to choose your browser based on any particular capabilities, like Netscape's ability to do all these plug-ins. I'm sure you'll see a lot more Java-enabled browsers and Java-enabled applications that act as browsers.

The other thing is, besides applets that are recognized by a browser, you can write stand-alone applications like word-processors and spreadsheet programs and anything else, actually, in Java. You have a built-in audience. As soon as people get to your site and they're running something that can read Java, then you don't have to build a user base by giving away pieces of stuff.

You'll see a lot where Zing and Reel Audio give away their clients so that people will buy their server stuff. You don't have to worry about buying a server to do Java. You just put your little applets in particular places on the server, which we'll talk about, and it gets sent along. One reason we like this is because it really is, in a lot of ways, bad for Microsoft and it's probably bad for companies I consider Microsoft-like: Silicon Graphics and [inaudible]. I hope people aren't in the room from those companies. It's okay.

Security. Basically when you compile it, it checks it to make sure you haven't done anything really weird that's going to screw other people up. When you send the application it's checked by the host computer. It's really designed for distributed environments, so you can incorporate things like remote procedure calls and weird terminals from old proprietary systems and you can probably write a Commodore emulator and run old games on it. Who knows. I'm sure you'll start seeing *Space Invaders* in Java and stuff like that.

What we're going to run through now is lots of applications and we'll talk about why they use Java, why we use Java and what it does. Some quick ones: [inaudible] front-ends. Even before Oracle officially licensed Java, we were starting to play with it because we have a

particular customer that runs Oracle databases everywhere. We wrote... basically, before, with CGI, you have these tools like *OraPERL* and *Wow*, which is *Web Work* or *Web*, that do things like go to the CGI, which turns everything like your little dialog box and buttons into SQL queries, sends those to the Oracle SQL server, finds the data, sends it back to CGI, which prepares it and then displays it on the screen in HTML 3.0 or however you defined it.

We've been doing that stuff for a while, and as soon as Java came along we knew that this would be a great way to break people of all these proprietary database interfaces developed in Visual Basic, which are a pain in the neck.

A quick particular client story. We have a very large customer that writes their own absolutely everything. They wrote their own e-mail program. They wrote their own spreadsheet program. Everything is called... it's the Coca-Cola Company and what they've done is everything is called KO something. It's KO-Anywhere like PC Anywhere; there's KO-Mail and KO-Office and there's KO-everything.

Now, they have teams and teams of programmers writing proprietary stuff who work with all their proprietary stuff. What winds up happening is that they rewrite all their CAD programs to do store-design management stuff, and it's kind of ridiculous.

When we saw it we were like, wow, this is pretty amazing. Do they actually know that by letting Web-based people in here, they're kind of undermining all these projects. What you were able to do before, like with these store management programs... And a slight sidetrack: there's a huge industry out there, I'm discovering, in how stores are laid out.

They define this amount of shelf space as a certain amount of money per year, and if Wrigley's gets that spot — there are all these incentives to have this spot — they build the casing. They're convinced there are only four different ways you're allowed to display Coca-Cola products within a store and it always has to be Coke and then Diet Coke and then Sprite and whatever. You'll always see this everywhere.

Anyway, people wanted to use this program remotely everywhere. They wanted stores to use it; they wanted their sales force to use it. So they had to distribute their own proprietary program for everyone and then every time there was any kind of update, they had to redistribute that and had to distribute files in this format or whatever.

Well, we wrote kind of a simple Web hack of that. What you would do is view things on-line as GIFs; then if you want to see this sort of CAD-type program to walk through it, you would click on it, it would come, it would recognize the MIME type and launch that particular application. They would still have to have that proprietary client application to actually view these files that'll allow you to look at and turn the store's models around and all that stuff.

Well, with Java all you need to do is send a very small application that only needs to open that particular type of file and display it and allow you to manipulate it. So all these coders with walls of Visual Basic books, if they go back to the drawing board and just port some of these to Java and learn Java, every time they have a new feature or want to do anything interesting, they just send along a new application actually to the files.

When it comes to [an] Oracle front-end, they write it in Visual Basic, define all the little widgets and how things look on the screen, but everyone gets the same thing. Whether you're an advertising agency that wants to check sales in a particular region based on an ad campaign or if you're a bottler who wants to know how many crates of Fanta Banana you've distributed to Red Lobster in Jackson, Mississippi, you still have the same interface. This way they'll be able to write very small interface programs to send to particular groups that can only see the data that they want to use. So it's a really interesting process.

Games — you're going to see millions of games. There is a great company that's here — I think they might have a booth — Dimension X, who has probably the niftiest Java site out there. It's called *VectorMan*, which is www.vectorman.com.

This is one I wish we could show you but we decided after I talked to Arthur [van Hoff] — he said they're moving everything from alpha to beta and he said just use Netscape now, don't use HotJava for your development. We decided we're only going to show you things that are beta and not alpha. Hopefully they're going to support that, but when you get to the site they've really done animations written in Java that look like the beginning of a Sega game. There are balls that fly in and sound and rotating things and lasers and all that stuff. It's really impressive.

It's one of these things — right now it's for marketing, a stand-alone Sega game. Well, why not actually keep going and write the whole game in Java. Charge people a couple of cents for usage; you know, when you're at the site you get to run through the thing. This is the kind of thing that [inaudible] will allow, where you'll be able to set up an account with Sega so you just play the game when you get to the site and they'll deduct it from some kind of bill. Who knows?

Software sales, again, charged by the usage of an application and groupware. I'm sure some of you work for organizations that have spent an awful lot of money on Lotus licenses or Novell, whatever their group stuff is called. You probably didn't need to, but it's a good steppingstone to real distributed applications, which you're going to start seeing more and more with Java.

M: [inaudible]

David Levine: That's a good question. Mostly the programs... [inaudible] can make the programs disappear. When the class comes in, I guess you would have it. What would you do with it?

M: [inaudible]

David Levine: There are stop controls and all that stuff and it recognizes when it's there and the program starts and the program stops. You can have the program die, become ineffectual.

There is the question of reverse engineering. It's probably easier to reverse-engineer a Java program than a C or C++ program at this point. So right now it's certainly not as robust a commercial application that way, but the class does come in to your computer and while it's running I imagine you could monitor the activity, you could sniff it.

M: [inaudible]

David Levine: That's the thing that's changing. That's one thing I've been actually wanting to address for us for the company that's doing this stuff. But it's really changing the way HotJava, the way Netscape actually used the classes and where they put them. There's a lot of talk about that. Do you let classes stay there? Do you let them stay in the computer? Do you automatically get rid of them because maybe there is some kind of time bomb in it? There are garbage collections that never [inaudible] reallocating and all that stuff.

I think probably the jury is still out. I think we kind of have to wait and see what the Sun developers decide and what's going on in the [UseNet] Java newsgroup. That's something we don't really know, but I'm definitely going to keep an eye on that.

M: [inaudible]

David Levine: He said there were rumors that the reason they didn't have Java in all the 2.0 beta releases and quickly sort of redid it... Sun released it for a day, and we grabbed a copy and it was great, but then it disappeared for a while — and, like, why did it go away?

Then they released a Java version of Netscape for Sun and non-Java, and there were security problems. I don't know exactly what those were. I imagine that Java is very scary to a lot of people. The idea of allowing executable programs from anywhere into your computer is scary. Who knows what it's going to be doing.

If you're worried when you register your Windows 95 about Microsoft finding out every application you're running and sending information to these other companies... Well, Microsoft at least is monitored by the Feds and all that stuff. If you go to a hacker site in Finland just to read some of their C source code to do stuff, you can imagine that they're probably checking you out and maybe... there's probably going to be a lot of that going on.

All the issues are not resolved. What probably happened is that they changed a lot between alpha and beta when they released Netscape in terms of where classes go. Just so you know — to backtrack a little bit, which Matt is going to talk about more — what classes are: Basically there are two types of files with Java. There's ".java" files, which are your source code. After you compile them you get class files, which are what you actually send to do the work.

Netscape changed really quickly how those classes are recognized by the browser; they have this weird file that recognizes particular classes. Originally they said you weren't going to be able to send your own classes, you were only going to use basic ones that they provided. There's a guy to talk to about it. His name is [Kipp Hickman] and you can just look at his page — I think it's kipp@Netscape.com. He's answered all our questions so far; he's been really helpful. He's the main engineer who incorporated Java and he could probably answer the Netscape -situated questions. That's just a resource.

The next thing I was actually going to get to is resources. The comp.lang.java newsgroup is really good. When the Netscape was released, everything was crashing. I don't know who actually reads Read Me files when you get new applications, but they have this weird file called the [Mos2.0] beta file. You have to put in your class path, which is defined in your [.chsrc] file. Who would have known?

So everything was crashing. I looked at the UseNet Java newsgroup and, of course, that's where people will be telling you what they've done, so that's a real good place to post. Don't use the mailing list that Sun set up because those have just gotten kind of out of control.

M: [inaudible]

David Levine: It's absolutely true. What you would do is you can set... they have a couple security settings which allow applets to do... like, you can get the browser — and this is kind of a hack because I don't really explain what it does — but they allow you, when you first launch the application, to allow applets to do certain things or not do certain things. So if you allow the applet to contact other hosts, then, yes, that kind of thing could actually happen. There's no question.

I run applets in unrestricted mode because we have computers that are just open... a lot of our computers are just open on the Net and we've basically decided we have to do business that way and back things up and just know that at some points we're probably going to have to do a lot of — you know, there's always a balance between security procedures, precautions and getting work done. So basically if you have computers within a sensitive area, you would proxy things at the firewall — you would proxy your job applets at the firewall.

But definitely when you first launch HotJava select the most secure, restricted applet load that will only allow applets to run on a local computer and not contact other computers. So that's basically their quick pseudo-hack. I mean, if you didn't know that and just said, "Oh, I want it to be able to do anything" — yes, you are definitely opening your network up to risks.

M: [inaudible]

David Levine: It's the same in Netscape. When you first launch Netscape there's a little dialog box.

M: [inaudible]

David Levine: Rating. Oh, that's interesting. In terms of rating content for, you mean in terms of...

M: [inaudible]

David Levine: That's interesting. I was just interested in the idea, I guess. It's a really good idea. I would suggest it to the Java group. It's a good question. Who would rate it. When you produce an applet and you send it... that actually is something that they were talking about on the Java list — that would allow you to set up certain directories and certain types of files you would be able to keep and certain you wouldn't be able to keep and all that stuff.

It is a discussion. It's just that this stuff is so new I haven't been able to track everything, but now that you mention it, people are talking about that — allowing certain things and not allowing certain things. I imagine what's going to happen is that more will be allowed universally; and home users and everyone else will kind of take their risks. The real companies out there who are worried about more security problems will hold Java off.

The reason it's not as much of an issue as it should be is because basically no one is secure right now. How many people out there let their users go to college FTP sites and download whatever they want. They see this fun stock-analysis tool and they pull it in and the corporation doesn't have procedures in place to only allow — at the routers or at the firewall — people to go to certain sites. So people are downloading crap all the time and people are launching them on their computers and there are virus problems in corporations and they're sniffing problems in corporations and snooping problems.

That's what it's all about. Right now nothing is very secure. We do a lot of security stuff that you don't read about, a lot is covered up, but there is a group of Russian hackers hanging out at a major financial firm downloading... they actually pulled about \$20 million of transferred funds over the last six months and the way they're trying to find these people is by monitoring the Russian language networking newsgroups.

There's so much going on that any language that's actually designed, in a sense, to be secure, with security in mind, which C and C++ aren't... the idea is that if the job is taken seriously as a financial tool and as a real tool for corporations to develop in, then people will build their own systems and defense systems and use systems with security in mind, to allow things and not allow things. That's really the answer.

Just to give another quick example. When we are called in to do security analysis for some of these big companies, we go in, "Oh, we just want to spot-check and make sure things are okay." They have a room totally full of modems taking up the whole local exchange — maybe it's 659 whatever with *Desk Log-In* that access all kinds of stuff around the network. And

they're saying, "We put in this Internet connection, what's going to happen to all our stuff?" And we're, like, dialing and changing their stock prices and stuff.

It's just that security is an issue, but I think Java will be a good security tool. SATAN is a real good example. People were scared of what it was going to do, but it's a great security tool. And Cops and everything else. You want to hack yourself and figure out everything that's wrong and fix it and not worry about the fact that other people have ways to get in for right now.

M: [inaudible]

David Levine: Well the applets are very simple. I'm not sure what you mean. If you send a ticker...

M: [inaudible]

David Levine: Are you speaking as a user, like the end user out in the world?

M: [inaudible]

David Levine: All it's doing when you send an applet, you define everything that applet can do and if your applet is sitting on the server, it's being requested, it's being pulled in the same way every other file is being pulled in, using HTTP. So they're requesting a sound file, an HTML file, and a class file and then it's leaving you and going there.

So it's not... you're defining what that applet can do once it's on the other end. You're not opening anything up except by giving that applet certain particular behaviors that do particular things. Now if you're letting that applet talk to your server in sort of a constant... maybe a stream or something that's sending constant data, then, like anything else, whatever port that is running on, whatever that's looking for and allowing, then connecting back to your server in a continual way, it is conceivable that someone can analyze what it's doing and send those same codes to your server.

But it's really no less secure than HTTP. I mean, if you're running a server, that either better be on the other side of a firewall than your important stuff and just being backed up and [you] say, well, if someone really screws with it, it means I just have to rebuild the server; or you're proxying everything at a firewall and the server is inside and not actually taking any direct connections. They're actually being made to the firewall, the firewall is asking the server stuff, the server is telling the firewall, the firewall is telling the end user. Those are your only two ways of being secure.

So whatever you're doing with Java on the side, if you think about it, it will probably help your security a little bit. If you don't think about it, it's not going to kill you if you're not already vulnerable.

Now, Matt actually gets to do some of the fun stuff.

M: [inaudible]

David Levine: That's an interesting question. You could do packets of something. Firewalls — there are an awful lot of different kinds. There are commercial ones and some that you're able to do a lot with, but that's something to talk to your firewall vendor about how to do it. I can't imagine that there's a commercial firewall product that wouldn't allow it or disallow it, that wouldn't make sense. But you're going to make your users real upset if you start blocking all

the class files with the firewall, but it's reasonable. If they're supposed to be in a very secure area, I would imagine that would make a lot of sense.

What we are going to do is Matt is going to run through a particular... He actually got this — just so you know with this change and the problems it caused — basically, we finally got the Netscape version of Java working with our old applets Sunday night around midnight. So we had yesterday to then try to convert them all and we got a little bit done. It's not as functional as we'd like, but Matt's going to show you a little bit about it and then I'll come back and show you a lot of sites around the Net and where to find stuff and why they did it that way. So here's Matt Davis.

Matt Davis: Another question I wanted to ask, of those of you who have done C and C++, have you actually done any object-oriented programming? How many of you have done object-oriented? Okay, I should probably kind of explain what object-oriented is. What about a show of hands of how many people have kind of a good idea what object-oriented programming is? Okay, that's most everybody.

Essentially everything in Java is object-oriented, almost everything. The only things that aren't object-oriented in Java are primitive data types like "int" for integers and short and long and that kind of thing. Those aren't object-oriented per se, but they're included in the language packages. Almost everything you do in Java, if not everything, is included in a whole package library and they're called through objects.

The whole Java construct centers itself around several different classes, and when you want to use something in that class, you have to create objects from those classes. When you write your Java application you call in... like you would use "include" in the C or C++ code, you would do the same thing with the Java applet, only you would only call the classes that you want.

What I want to talk about really quickly is just the process of what you would do, what you would want to do to get Java to work on whatever platform once all these developers get Java working on PCs and Macs and UNIX a lot, lot better.

We're at a pre-beta stage right now. We've been having tons of problems with Netscape and all that kind of thing. I'm not even 100% sure that what we got working 30 minutes ago, or an hour ago, is going to work right now just because Netscape and Java have been completely unpredictable and they've pretty much said the same things to us, the Netscape people were just like, "Well, we don't know."

What we're looking at up here, this is on the resource sheet I believe, Gamelan — that's how it's pronounced by the way, with a "j" sound — it's a musical ensemble — not "Gamelan" like the "g" sound in game. This Gamelan site is a really great resource, so when you're getting into writing your own Java or getting your programmers to write their own Java, I would definitely, definitely look at this place.

They keep updating and they have forms for people to come in and submit their own applets and applications and sites. In case you don't have it, it's www.gamelan.com.

What you see right there is an actual Java applet. The one at the bottom of the page is really cool. I can grab this thing and throw it. So this application is running on this machine right here.

What they've done, when they wrote this application they called several of the class libraries out of the Java development kit, which is the distribution of the programming language and the compiler — or it's a pre-compiler really — they called the classes that they want. They incorporate the methods that come out of these classes into their code, they call on the different behaviors of the classes in their own objects, then they bundle them all together and they send them out over the Net to us. This little program has been interpreted by Netscape.

Java is an interpreted language. It's kind of like, some of you are familiar with HyperTalk, that's the language for HyperCard on the Mac. SmallTalk, PERL is kind of the same way, it's really easy. Some of them get really ridiculous. AppleScript really bothers me sometimes. I mean, they're trying to make it really easy for you to do programming and trying to make things a little bit more like English, which sometimes works against itself.

But the point behind a lot of those pseudo-scripting languages, pseudo-programming languages like Tickle and SmallTalk and PERL and HyperTalk is that they're interpreted, they're not compiled completely. They run dynamically. And that's kind of how Java works. So on this machine, for example, we would pre-compile our classes — really what it does is it goes to the Java development kit, it gets all the classes that we asked for and it packages them up for us. Then when it gets downloaded to a site, the interpreter or the browser — which would be HotJava in alpha cases, I don't know if a beta will be out soon — and Netscape in this case further interprets the code.

They're called "byte codes." It interprets these byte codes that were created on the server machine to run an applet. It's just like you would put an applet on an HTML page, just like you would put an image on an HTML page with tags. That's how it works. It's really easy. It's becoming increasingly easier because a lot of people are writing their own applets — like animation applets, like the one at the top here. I would bet this is the animation applet that the folks over at Sun wrote. It's like this package animation thing — you can download it, you don't have to do any coding at all. All you have to know is how to write the HTML for it.

M: [inaudible]

Matt Davis: Just like any animation with frames and stuff like that. However, there are methods in Java to do native graphics. Java has a whole class library of what's called "graphic graphics." It's actual drawing; you can draw your own lines and objects and shapes. In that case, you are doing real animation where you're not using frames, you're using actual animated objects.

M: [inaudible]

Matt Davis: I don't know how complete it is really, because there isn't a whole lot of documentation for it. That's one of the biggest problems that we've run into. At the Java site, they have this Java development kit and they've got this listing of the classes and they've got these weird Hypertext lengths and they don't describe what the classes really do. They kind of do in a sentence and they kind of describe what you have to use, but it's not described very well and it's not described in length. There are a couple of resources that are on this Gamelan that are really nice.

The way that all these classes are being developed, they're kind of taking the approach of... Oh, here's the Sun Home Page. Hopefully, they have a little animation applet here at the bottom. It kind of looks like they're creating all these class libraries trying to foresee what people are going to want to use, which is how they've been developing this graphics library.

They have this whole Net library which contains URL redirection objects and that kind of thing. What we're looking at right here is the Java site that Sun has. There it is. Okay, that's working the same way as that first. (Can everyone see that? Do I need to move it to the top of the screen?)

The Java site is also a good resource for doing things. One of the things — when I was trying to learn Java, I'd get very frustrated when they'd switch right in the middle of me trying to learn it — was there are some pretty good tutorial-type places at the Java site. So that's

another place that you're going to want to look. This tutorial, this Java programmer's guide is pretty nice. That's in the Sun, the Java site. That's just java.sun.com.

They use this little trail map idea to get you through the site, kind of like you were hiking on [a trail] or something. Here's this little guy, this little Duke guy, and he's an animation, there he is. That thing is called Duke.

This is a perfect example of the kind of problems that we're having with this. We've talked to Netscape, we've talked to the people at Sun and they're just like, "Well, it's just error messages. You can't do anything about it." There's like a ton of them, so I'm going to get off this page quick.

M: [inaudible]

Matt Davis: Oh, really. You mean the show toolbar thing? I need three hands.

M: [inaudible]

Matt Davis: Well, Java is loosely based on C and C++ — a lot of people probably know that. The people at Sun kind of took C++, they took, like, the structure of C++ and they took some stuff from C; they took a lot of ideas from objective C. And what they did is they kind of modeled it after those — the previous API — and they modeled it after the library structure of those things. But who knows what's going to happen.

You're right, it is kind of weird, it's kind of scary. It's poorly documented, it's still growing. They completely changed their class structure when they went from alpha to beta. The only thing I can say is we need to wait and see, and that's what we've been saying for a lot of this stuff. It's just kind of like, well, maybe it'll work next month.

M: [inaudible]

Matt Davis: That's the whole idea with it. The kind of things that the class library in Java includes are stuff like GUI, widgets and things like that. I mean, the HotJava browser itself was written in Java, it was not written according to Windows at all.

M: [inaudible]

Matt Davis: Moving on a little bit, trying to get down into the nuts and bolts of what Java actually is and how things work, we're going to show you a little something of applets. That's Netscape *Frames*, by the way, in case you haven't seen it yet. With this Netscape a lot of these are ex-Window errors. I don't know what's going happen when they start trying to do Mac toolbox stuff. That's going to be really interesting.

Everything that we see here except for the graphic in the middle [inaudible] is all Java. This is the one that we, all day yesterday, got off of the beta. The music that we hear, we were talking before about having to download a sound machine for the Mac or AU player or whatever; we don't have to have that. Java is letting us stream that audio from a server and the Java application that's embedded on this page is playing the music.

It's coming straight through that application, which means we don't have to launch an external application. We can keep the images up on the page and use the sound to really incorporate itself into the page. I'm a musician and one of my biggest interests with the Web is trying to get music and audio really incorporated into the Web. Because right now it's not.

I mean, there are a lot of different things you can do with music and audio on the Web, but it's not nearly as incorporated into the Web as it could be, it should be, or as much as graphics are. So one thing Java is going to be able to do is what you see here. It's going to be able to really incorporate these sounds.

M: [inaudible]

Matt Davis: That's a dance suite that was performed at a recital of mine a few years ago. The thing you see in the middle is an animation like you saw before and it works the same way. The butterfly is just three frames of flapping its wings. I was thinking about this yesterday and last night that it's kind of neat that the variable... because of different things, the speed of the machine... that the performance of Netscape is letting the wings flap kind of more like a butterfly would really flap its wings.

M: [inaudible]

Matt Davis: Yes. Let me kind of explain how *Netscape* does that. That little [Mos 2.0].car file, it's kind of this weird... Netscape hasn't even explained officially what that little file is.

M: [inaudible]

Matt Davis: What the file is, it's [Mos 2.0].car, and that, hopefully, it'll be documented in whatever package of Netscape you download. But what that file does is it redirects call to classes in the Netscape browser to the interpreter on your machine and it works kind of weird. That's where a lot of these errors come from.

It's almost like it's this big hack file and it's just like Netscape said, "Well, we need to tell Netscape where to find these classes," or whatever. "We need to tell them where these classes are going to be, so we'll put in this file and it'll redirect things for you."

But you're right. It just takes these methods that it's inherited from other classes, larger classes, and plays the sound file. For example, this little audio applet that we heard that was playing uses two classes.

M: [inaudible]

Matt Davis: Yes, the very first example. This is really kind of hard to explain without a whiteboard back here or a chalkboard or an overhead projector or something. It's really good to look at the source file here; and I've commented this code kind of sparsely but a lot of the code out there is commented very, very well. A lot of the code that I've come across is, but a lot of it unfortunately is not. I think there's an example in here of poorly documented, undocumented, code. That wasn't mine, it's the last example.

With this `auto audio.java` — that's the code, the name of the source file. If you look down below these comments, it says `import java.applet.applet import java.applet.audioclip`. That does two things. It imports two classes and only two classes from the class library of the Java development kit.

I could also include a wild card in those imports, so I can import an entire library of classes if I want to. I can import all of `java.applet` and just say `java.applet.*` and get all of those classes, but I didn't need to. I only needed to use the applet class so, I just imported that one.

Same deal with the other one. I just needed the audio clip class, so I just imported that one. What that does is it allows me to use those classes in my applet, but I still have to create objects in my code to be able to use the methods and emulate the behavior of those classes.

If you look down to about midway through the page, you'll see a comment that says an object sounds of class audio clip. Right there is where I've created an object from the class audio clip. And then through here, down at the bottom of the page, you'll see where this actually gets played. Sounds.play is... play is a method within the class audio clip. I'm calling that method through the object sounds or in the object sounds, so it automatically plays it. It's really that easy. This code is barely two pages; I mean, it's really a page long.

M: [inaudible]

Matt Davis: Yes, you can. In fact, another example, if you go down below that audio clip object declaration, the one right below it is string music file. There's a data type in Java, this is really nice, too.

One thing that the Java developers really tried to do for you is make things a lot easier because they know that you as Web developers just want to get your stuff out. And a lot of the Web is encumbered with a lot of difficult things to get stuff done.

Java has incorporated a lot of simple and robust procedures to help you do that; for example, it does its own memory management. There are no pointers in Java at all. There is no pointer arithmetic at all. Java does its own memory management; it does its own garbage collection. You never have to worry about that, so you never get any loose ends in your memory allocations whatsoever. You're never bothered with it.

Another thing that Java has put in here that's kind of cool is the string; if you do Macintosh, like HyperTalk stuff, you have strings. You don't have to do an array of strings to have a string, like you do in C. In Java, you can just have a string variable and it holds a string right here; it holds the location of the AU file that we heard. So in that example I just created that variable and then in this method which is right below it, I assigned it this parameter file.

If we were to look at the source of this page... this is kind of hard to read from in the back, but this right here, here's the tag in HTML that tells the browser to request the sound applet. The first part of it is, of course, applet — that's the actual tag. Code is the name of the class that's pre-compiled from this source code. So after you write this source code you pre-compile it with the Java compiler and you put it out as a start-up class file, which is what is up here; audioauto.class actually gets downloaded.

Code base is the directory that the browser should look in at the server root for the class that it's retrieving.

M: [inaudible]

Matt Davis: Going down the applet tag there, there's a width and a height. If you're doing this, Netscape will completely just break if you don't put the width and the height there. It's a little redundant because in the applet when you write the code you do that anyway and you re-size your applet, but Netscape for some reason wants to see that.

This is the one that I really want to talk about, this param. One of the things that you can do so that your applets are portable and you can use one applet over and over again for several different applications is use parameters. That's what I'm doing here. So I tell... if we look back to the code in this INIT method, I get parameter and the parameter name is file.

If we look up here in the tag, we tell the browser that the parameter's name is file and we give it a value. The value is the absolute path of the sound file, the server route. Then you go through this code and it just runs it.

You will notice that at the very top — not the very top, a few declarations down — there's a thread declaration. That's another really, really cool, awesomely cool, aspect of Java is that it's multi-threaded, multi-threadable. A lot of things are not; most things are not unless they're explicit.

Java has threading automatically in it, and you'll notice that I didn't have to import any special classes to use thread — it's all there automatically. I create a thread so that sound file is playing in a thread. Does most everyone know what I'm talking about when I say threaded applications and multi-threaded?

It's concurrent to other threads, so it doesn't have to steal processor time. So you can have several threads running in parallel together and in parallel to other processes on your computer.

What that means is that I can have a whole page of graphics or something and I can still have my animation playing without holding up any of the other graphics that are loading, any other animations that are going on.

Everything that you see on this page is threaded. This animation is not held up. It doesn't have to wait for the sound file to play; the sound file doesn't have to wait for the animation to get loaded and to start playing. Since they're threaded, they can be multi-threaded and they can do something at the same time.

M: [inaudible]

Matt Davis: There is the animator applet that I had talked about before. We didn't use the animator applet because that's one of the things we couldn't get to work. For some reason, we can't get the animator applet to work at all, but Arthur [van Hoff] has written this animator applet that has got that kind of thing.

You can synchronize audio to frames and things like that, so depending on what frame is going in your animation, you can synchronize a specific audio file to that frame. In that sound that you're hearing, that's actually a bunch of different sounds that are combined, that's not one sound file. That's actually — if you look at these different parameters — that's a list of AU files that are... they're not [inaudible] with the frames or anything like that, but they're just synchronized with the frames. It'd be really cool if they had like [inaudible] kind of stuff, but I don't know if they do. They might. This is just a sound file playing with the Java applet.

Windows 95 can handle threading. Windows NT can handle threading. The Macintosh OS has an extension that handles threading. You have to install it. There are several Macintosh applications that are threaded. Of course, when Copeland comes out we'll all be very happy with Copeland's multi-threading and all that other fun stuff. That's why we don't see a Mac OS port of HotJava or HotJava-enabled Netscape yet because the Mac OS isn't compatible with what Java can do right now. That's too bad. Apple needs to get off their butts and get Copeland out.

M: [inaudible]

Matt Davis: Sure, sure. As I mentioned before, these classes contain methods; and one thing, if you're fairly familiar with object programming, you know that you can override methods in classes.

Now what we're doing here is we're just overriding these methods. `INIT` and `start` and `stop` are built-in methods to the applet class. That's the class we imported in the very beginning. Those happen, anyway.

What I'm doing in this code is I'm overriding those methods and putting in my own directions, so when the applet receives the `INIT`, when that behavior of the applet happens, I'm telling it to assign a string to the music file string, I'm telling it to do something with the thread here when the `run` method happens. That's part of a larger class.

If you look up at the top, I defined the class `public class audio auto extends applet` — implements `Runnable`. What that means is that it extends the applet class. This is a class that I'm creating. I'm importing the applet class from the Java development kit class library. I'm extending it; it extends, it inherits the methods from the applet class.

I'm going to use those methods and since I want to use a thread, since I want my applet to run a thread, it implements `Runnable`, which is another part of the great picture. `Runnable` is not a method, `Runnable` is a class. It implements `Runnable`, so I can override the methods in `Runnable` to use them. One of the methods in `Runnable` that I'm overriding is `run`. When you use threads, that's like the big thing — that's your main thing.

M: [inaudible]

Matt Davis: What happens there, there's a large class library that your applet automatically has. You don't have to import anything. It automatically has all these classes in it, and that's the way they've set up Java to be. Whenever you have any Java application, you automatically have access to this certain amount of classes and there is a hierarchy of those classes. There's a whole hierarchy of classes that they use.

This is really poorly documented — I really wish it wasn't like this. `Runnable` is actually not part of the applet. `Runnable` is another class. This is what I'm talking about. These different packages are what you import. In this applet package, we import this applet class. There's a good diagram of this hierarchy in this trail guide. What's it's doing is it's actually using something that it automatically already has to be able to run threads and that's what this implements `Runnable` does.

M: [inaudible]

Matt Davis: Yes, it kind of is since you're not actually explicitly inheriting `Runnable`, it is sort of like that. If I did not put "implements `Runnable`" on there, I couldn't use `Run`. `Run` is part of `Runnable`. `Run` is where everything happens with the thread. I can use `start` and `stop` because they're part of applet and I can make calls to the methods in `audio auto`.

M: [inaudible]

Matt Davis: Yes. You can capture events; yes, you can capture that event and tell it to stop. So if you look down here, this is actually a version of the code before of what's actually on here in this `run` method that I've overridden to tell the sound to play. I tell it `sounds.play`. Do that method, play the sound. The class takes care of everything for me. I can capture a mouse click.

M: [inaudible]

Matt Davis: Yes, like a mouse entering the area, you can tell it to stop.

M: [inaudible]

Matt Davis: You mean in this? It's the last example? That's something that we actually picked up from somewhere else.

M: [inaudible]

Matt Davis: You're actually downloading three. If you'll watch, what's happening there is that applet is in four different places on the page. When you move the cursor over the graphic it pulls up another graphic, so it captures that mouse inter-event.

M: [inaudible]

Matt Davis: Yes. It's not so much that it's cached, it's that it's all been downloaded, which is the beauty of Java as well. Everything gets downloaded first before it gets executed, so that stuff isn't happening over any lines right now. Netscape isn't making any calls to any page. It's already downloaded these applets. They're executing.

David Levine: [inaudible]

Matt Davis: And that's an option. You don't have to do it that way either. You don't have to stream in all your graphics files like this one does. You can just have the browser download the entire applet and all the graphics files before you ever see anything and then launch the application. Which is like the Gamelan site — that animation is that kind of thing. It doesn't load every frame as the applet gets loaded. It loads the entire applet and then executes on the page.

What I should say about these things is that the best thing is to go through and just look at people's code because, like I said, the documentation is kind of sparse. A lot of that trail map isn't even finished, they haven't finished it yet. Things are changing. You just have to go through... Question?

M: [inaudible]

Matt Davis: Well, that depends on how much you have there. It's just like having several graphics without Java on your page.

M: [inaudible]

Matt Davis: They could.

David Levine: From my experience they'll complain if you don't give them something to do as other things are coming. If you look at the Sun Microsystems page, with Java they have a lot going on, probably too much. I mean, it's really enormous, but they do have some things starting to work before other things happen, like they have the Tumbling Duke come in.

After about five minutes, if you happen to still be on the page, you get the Tumbling Duke come in. But if you've already left, then you just don't know that was going to come. So it's important to [inaudible] when you design these things. And www.dnx.com, which is the Dimension X site, they don't give source for anything, which is kind of annoying, but in showing off they do have a lot of progressive rendering-type things. Where you would have... they have a lot of different streaming animations and stuff like that.

So it's a really good thing to think about and one thing I'm really looking forward to is playing more with the streaming capabilities. The other thing is once it is there, if you convince them to wait — like if you've given them stuff to do while they're waiting — when they go back to the page, you can just go to one page and come back and it should all still be there.

What's happening here is it'll take you a little while to re-draw things, but it actually should — if you've just hot-listed everything — you should be able to go right back to it once you're done with it.

M: [inaudible]

Matt Davis: Well, our URL is www.butterfly.net and we'll have pointers to a lot of different applets that we do and everything else. Yes?

M: [inaudible]

Matt Davis: These are 2 and 3K, just the applets themselves. That's not including the graphics and sounds they have to download.

M: [inaudible]

Matt Davis: Yes. It's just like creating your own classes in C or C++. You can create a class that's not an applet and create your own class that a user could download and use. It's probably possible to create if you have a very big, something that uses a lot of different things in your class or native methods or something like that. You could have the user download this class, put it somewhere and then have another smaller applet in your browser look for that class on the user machine. That seems like something that would be possible.

M: [inaudible]

Matt Davis: Java workshop? As far as the first question was, if you could optimize Java code to use the least number of byte codes? That's not something that I've tried, so I can't say firsthand, but I haven't run across anything like that, like going through code and going through this and that.

I haven't come across anyone who talks about it or mentions it, so it could be either something in development or something that just isn't possible yet or something that just nobody does. As far as the second thing, like a Visual Basic kind of environment where you could build Java applications, I'm sure that's something that people want to do because you can create a complete GUI interface with Java. I'm sure that's something that's forthcoming.

M [inaudible]

Matt Davis: They don't live there forever. They act just like anything else that you would download with a browser. They get cached, the executable would get cached as long as you tell your browser to cache it.

M: [inaudible]

Matt Davis: You mean the source class itself?

M: [inaudible]

Matt Davis: Right now there's not a really easy way for applets to talk to each other; if you're talking about, for example, they download a version updater applet or something. Is that what you mean?

M: [inaudible]

Matt Davis: He's concerned about upward compatibility and versioning classes that people have already written and distributed, and if there's something built into Java to do that. Right now it's just not something that people are addressing. It doesn't look like Sun has really been addressing that, or any other developers.

M: [inaudible]

Matt Davis: I think once they get their own frozen API, actually frozen, they're going to start worrying about that more. I think Sun's big focus right now is to just get past pre-beta into something that's actually usable, because right now it's really iffy.

M: [inaudible]

Matt Davis: The only kind of development tools you have, you mean as far as like a...

M: [inaudible]

Matt Davis: Okay. At the Java site, which is java.sun.com, all that information is there and all the different versions of the pre-beta development kit are there in a format that you can download and unpack and use on your machine.

M: [inaudible]

Matt Davis: There are a couple of tricks. If people don't explicitly put a little link on their page... a lot of people will put a link on their page to download the source, which is really nice. One thing that we've been discovering is that a lot of people use the same directory structure.

M: [inaudible]

Matt Davis: So if you just kind of mess around with their directory tree and try to find something, [most] Web servers won't let you do that, but a lot will.

M: [inaudible]

Matt Davis: It may not be there, I don't know.

M: [inaudible]

Matt Davis: I'm not sure I understand, you mean, what they're developing. Well, the methods happen. They're embedded in classes. Classes have methods. A class has a behavior and to get that behavior it uses methods, so, in answer to your question, the methods are the most stable

right now because they may add classes. Do you see what I'm saying? Methods are included in classes.

M: [inaudible]

Matt Davis: No, you don't have to define methods. You can override methods, but you have to define what classes you're using and you have to know what methods... this is one of the things that's not documented real well is what methods and what classes are available to you.

M: [inaudible]

Matt Davis: There isn't one. There isn't a class browser, as far as I know, for Java. Not in the same way that a Think compiler would have a class browser to go through the classes and find methods. You kind of have to dig and you kind of have to go through the API documentation that Java has up at their site and just kind of look through it and try to find what you're looking for. It's not really straightforward right now, but it's there. You just have to dig for it.

M: [inaudible]

Matt Davis: Yes, that's something — like we were talking about before — that's something that you can tell your browser not to do.

M: [inaudible]

Matt Davis: Yes, that's the idea. That's the whole idea that... oh, you mean from your applet?

M: [inaudible]

Matt Davis: Well, that's going to depend on two things. That's going to depend on first of all how you have your system set up and what kind of system you're on anyway. If the applet is going to be able to write to whatever file system that it's trying to write to. That's another security issue, of course.

M: [inaudible]

Matt Davis: Yes, that's just going to be something where there's going to have to be some kind of interface with the applet or the browser or something that just says, "Ignore this, I want to write to my file system with this applet." There could be methods in the applet that just ask...

[Tape change]

Matt Davis: ...either all CGI or all Java.

M: [inaudible]

Matt Davis: Do you mean dynamic creation of your pages? Well, the way that Java works, you could use Java to write those CGIs anyway. Do you write all your CGIs in C or... ?

M: [inaudible]

Matt Davis: Java works as a programming language just as well as it works as a Web-executable content language. So, yes, you could just use Java. In fact, if you look on that trail map on the Java site, that trail map programmer's guide to Java, there's a section using native resources like C libraries and stuff like that, so if you had a C library defined with your CGI stuff in it, you could use that with Java.

M: [inaudible]

Matt Davis: Well, one of the really nice things about that is that since it's interpreted, you could use all those different APIs concurrently, if I'm understanding what you're saying right.

M: [inaudible]

Matt Davis: Okay, what's he's talking about is essentially the same thing that's happened with the Microsoft API — the same trouble that developers have gotten into now — which is having to use the Microsoft API to develop software that people can use. Because it's the biggest thing that people use as far as doing what this software developer wants people to do with their software, so they have to conform to Microsoft API.

Then we said that Java gets rid of that because it's a frozen API, it's interpreted, it's cross-platform, very easily portable. But then what he's bringing up is that it would be very easy for a company like Netscape to create their own set of classes that another developer wants to use — some really nifty set of classes — and this developer wants to use them but Netscape doesn't license them. Then you've been caught in the same trap.

M: [inaudible]

Matt Davis: Yes, they could license the interface but not the classes.

M: [inaudible]

Matt Davis: How did I create it — that sound file? Originally, it was recorded from my recital and then I actually took that sound file and dumped it onto a Mac with *Sound Edit* and then messed with it like I wanted to, got the cuts where I wanted to put them, and then onto the Sun. I had an AIFF file.

Well, I went through several different platforms to get it to AU file. I had these AIFF files and we converted them to AU files.

M: What platform do you work on?

Matt Davis: There are several.

David Levine: That's been a big issue. Right now Java natively supports 8-bit, [inaudible].

M: [inaudible]

Matt Davis: Dynamic link. Are you talking about a CGI type of thing that's currently... ?

M: [inaudible]

Matt Davis: There's actually someone at Virginia Tech who wrote a Java applet that is embedded in an HTML page, just like all these other applets are, but it talks with an Oracle database.

One of the things that I'd really emphasize on suggestion is looking through these applets that other people have written and be able to see the kinds of examples... like this fellow from Tech that does charts on-the-fly from Oracle data. This is just an example of the kind of thing you can do.

With Java, almost anything you can think of, if you can program it in another language, like C or C++, you can program it in Java, which also means that you can make it executable content in HTML. It just expands the possibilities of what you can do.

M: [inaudible]

Matt Davis: I haven't come across anything myself, but I don't see why there wouldn't be. If there's a need for something like that, somebody's going to write it. It's not something that I've run across. Someone else back there had a question?

M: [inaudible]

Matt Davis: That's a good example of what's going on in the commercial Java realm. That particular demo is drawing something from a static file that is just replaying... there's source on the server that has a list of this information in a database-type thing.

I don't know exactly what's going on on the other end, although they do have an FTP-able version that you can download and run it all locally. But those files that it's reading can be constantly changing and they'll always read the new data.

There is actually a company called Market Vision, which is taking that kind of thing and they've written what they call a network utility in Java, which basically plugs — and they use the Netscape API, the server API, I believe — and kind of plug in this dynamic database thing. So you can devise your own [Bloomberg]-type system; you know, it's getting data from different places, putting it in the right files and your Java front-end is then reading those files. And every time it goes around it's gotten the new data. That's definitely a capability and now that commercial application developers are starting to write server stuff in it, you'll be able to buy things like the Market Vision Java utility.

M: [inaudible]

David Levine: I think it's always looking.

Matt Davis: You can tell an applet to locate a URL, if that's your question. You don't have to have a downloadable file.

M: [inaudible]

Matt Davis: Not if you're pointing to a URL that's being changed.

M: [inaudible]

Matt Davis: Yes, it depends on what you're pointing to. If you said, "Point to this document on my server," instead of pointing to a URL of a document that's being changed, then...

M: [inaudible]

David Levine: What the gentleman in back is saying is that someone's looking at this page that's dynamically getting information from a particular site. If I want to actually change where it's getting its information, how would I do that if he has the thing open all the time? If there is a constant connection and you break that, if you move that file that it's looking at, all of a sudden there won't be any data. If you put new data there, in terms of can you force in a new client that does very different things? I don't know. I don't think so.

You could build that into the application that it would listen for a command that says start totally over and get rid of it. Unfortunately, because we're in this transferring process, all the really cool stuff out there is still in the alpha form. There's a lot we could show you in terms of shared whiteboards and things we've done and things other people have out there, but it's just kind of a mess right now.

M: [inaudible]

Matt Davis: Yes, there are ways of implementing native methods that you can link C libraries, C functions with Java. Yes, there are ways of doing that.

Okay, if you look at the top of that icon [in] Java, you'll notice what I said I could do before, I did in this one. I imported the entire package; the entire Java.applet package contains a class called graphics and it also contains a class called image. So I'm just creating an object from the class image that I've imported because I used a wild card to import every class in that package.

M: [inaudible]

Matt Davis: Image is the class that falls into the package Java.applet.*.

M: [inaudible]

Matt Davis: There isn't. If you want it to just... explicitly, if you were worried about that, you could just import java.applet.image if you wanted to. Actually, I'm telling you the wrong thing. It's actually in "[auk]" — [java.auk.image] is the class and you could explicitly just import that class instead of everything.

A lot of people just import everything because they do it. In a lot of cases, you can just use an explicit reference and use... like here, down on the second page of that icon thing, the icon code, about halfway down where it says painting, that's a direct call to the method in that graphics class. So you can do it like that. See what I mean?

M: [inaudible]

Matt Davis: That's what that applet tag is. Is that what you're talking about?

M: [inaudible]

David Levine: I found it. It took me a while.

Matt Davis: The width and height and code base and all that kind of stuff.

M: [inaudible]

Matt Davis: It's really sparse. It's annoying.

M: [inaudible]

Matt Davis: There's a JavaNet — whatever. That's something else you can find on that API documentation page. Any other questions?

M: [inaudible]

Matt Davis: That's something that isn't fully developed by Sun right now. It's something that they've talked about. As far as I know, I haven't seen anything implemented to applets talking through TCP, but they say that that is going to be possible, that they're going to have applets be able to talk in between each other. Is that your question?

M: [inaudible]

Matt Davis: No. It will be possible. It will be possible.

M: [inaudible]

Matt Davis: Yes, pretty much. You can't talk, as far as I know... and this is something else that I just haven't gotten into... but that's pretty much the only way to get information is through URL and, like I said before, there's a whole package of URL stuff and Net stuff.

M: [inaudible]

Matt Davis: The file I/O stuff in Java exists. I don't think it's been developed to its full potential yet. The idea that Java is not a language that's been created explicitly for executable content. Their idea is that this is another object-oriented programming language and they're going to try to put everything in this programming language that's available in other objective C or C++ or anything like that. So that's the idea, is to have it be a stand-alone programming language. So yes, that's coming.

M: [inaudible]

Matt Davis: I wouldn't trust it.

M: [inaudible]

Matt Davis: No, no. You can do stand-alone applications for Java now. Is that what you're asking? Not using a browser to run Java ?

M: [inaudible]

Matt Davis: You mean, how would you run a Java application without a browser? There's a Java interpreter included in the development kit that interprets the applications that you've written and, of course, HotJava was written in Java completely and it does the same thing. In the old alpha version, the HotJava program actually calls on the Java interpreter and then all the other classes and the distribution, so you don't have to have a browser at all.

M: [inaudible]

Matt Davis: Yes, for the most part that's correct.

M: [inaudible]

Matt Davis: Yes, it just ignores the tag.

M: [inaudible]

Matt Davis: Yes. For the platforms that support Java, that's what they do. Because stuff was getting broken. That's what they did with the Solaris version and the Sun version. They have both a Java-enabled version and then a non-Java version and I expect that's what they're going to do for Mac as well.

M: [inaudible]

Matt Davis: I haven't done anything like that, no. Applets in HTML work fine.

M: [inaudible]

Matt Davis: No, I haven't worked with any.

M: [inaudible]

Matt Davis: Yes. There's not an .alt tag, but if you put something within the applet tag that's not part of the actual applet tag that does Java stuff, if you put something else in there like an image tag or something like that, that will show up instead if it doesn't have Java.

David Levine: Actually, a really good example of that is the spinning earth. When you get around to looking at it — I don't have the URL here, they have — if you're in a non-Java, it just shows the first GIF, it's image.source.earth1.gif. If you do have Java, it goes through the whole succession of images. That's the only thing that people complained about a lot in the alpha version before they set the applet-data type definition.

We do have to wrap up. There is contact information. Send us e-mails, show us what you're doing. We'll look at it if we can offer advice on fixing anything or whatever. I'm sure very quickly a lot of you will be a lot farther along than we are. Thanks a lot.

TUTORIALS
PUBLISHERS AND THE INTERNET:
IS IT THREATENING, OR IS IT THE OPPORTUNITY OF A LIFETIME?

SPEAKER
Larry Chase
President, The On-line Ad Agency

[The first few minutes of this session were lost due to recording equipment failure.]

Larry Chase: ... [You get] a little bit more elaborate and higher grades of data and collection services, but what you have here is essentially a product that you can get for free, and it does raise the issue to all publishers: How much did you give away for free and how much did you charge for it and, in fact, should you charge at all? And that's one of the things we'll talk about today.

I mentioned there are other services out there that offer something similar to this [inaudible]. You really do have to ask yourself, if I can get this for free, and another service charges me, maybe another \$5.00 a month for it, is it worth it? Is it worth a subscription to something else if I can get 80% or 90% of what I want from a site that's free? Publishers are grappling with this very problem.

There are numbers in the publishing field and in other categories of business called the 80-20 rule. And in this case, 80-20 is 80% of your revenue if you're a magazine or a newspaper, changes are plus or minus a few percent, but 80% of your revenue comes from advertising, 20% of it comes from subscription for a consumer-type publication. On the Web, there is some question whether that model will live. I'm seeing a lot of research out there that is suggesting that subscription models, unless it's in a very high-interest area, like a Lexis or a Nexis, that kind of very deep-dish data, as I call it, that you really need huge databases to access, there's some question of whether you're going to pay extra for a few percentage points more of information, particularly when everybody is fighting for your attention.

You know, some of you who came in here earlier saw that we were playing with a couple of cute images. One was that of a frog and we call him "Froggie," and Froggie is a Net surfer. And Froggie goes from lilypad to lilypad. Those lilypads happen to be your Web sites. In the case of publishers, the cyber-bait that is used to pull the frog into your Web site is content. Now, if there's a lot of competition out there, it raises the bar of quality of content constantly, in order to attract the appropriate frogs onto your Web site. You don't want all frogs; you're not all things to all people. You're probably going to address a certain niche. But, you will have to probably keep increasing the value of the information in order to compete with all of those other lilypads out there in your category to get them into your Web site. And one way to compete is to offer high-value information for free. And I think that's why some of these research reports are circumspect of the subscription model, because if you start charging for a service, and then a year out or two years out, the competitive bar has been raised to the point where people are now giving away information that you're charging for, you'll probably have an upset franchise, an upset subscriber base, and a diminishing one, at that.

I strayed a little bit off this here. We're on newspapers. I do digress a lot, but I do ultimately come back.

On newspapers, I wanted to show you a couple of the things that we use at the On-line Ad Agency for reconnaissance tools. One of them is a site called Newslink. There are few sites on the Net that have what I call "junction sites," if you will. We're up here in New England, you know, if you go out to New Hampshire for some fall foliage, if there's any left, you see these big

signs with pointers, like a 20-foot pole, and you have “Junction this way, Route 36, that way.” So we have these junctions with these pointers. Specifically, in publishing, there are a few that are very, very good tools for you to know about, if you don’t know about them already, and we’ll point them out to you during the course of this lecture.

One of them is, as I say, Newshare. Basically, it’s about as best a collection of newlinks — I said Newshare; I mean Newslink, I’m sorry — it’s about as best a collection of news-related links that I’ve seen down the Net. It covers newspapers, it covers Newswire and so forth and so on. Each industry, at this point, seems to have one or two or three of these junction stations where you can go for all the information on e-zines, and we’ll show you one of those later.

For automotive, if you’re in the automotive category, there are a couple of sites that basically say “Automotive Is Us.” You want to know about automotive or what cars are on the Net or who is selling used cars or where I can get tires for a 1955 Buick or whatever, you know, these communities, if you will. In this particular case it’s a business community. One of those communities is Newslink and it happens to be updated pretty often and we find ourselves visiting it with fair frequency.

The next one I’d like to go to is *The Wall Street Journal*, and what I’d like to point out about *The Wall Street Journal* is I think what they’re doing right here is they’re cross-promoting or cross-merchandising with the print edition of *The Wall Street Journal*, and that’s a very important point I want to make here.

The name of this seminar is “Publishing: Is It a Threat or Is It An Opportunity of a Lifetime?” It’s really both. *The Wall Street Journal*, I think, realizes it and they’re playing around with a couple of different models, as is the *New York Times* and other large newspaper concerns. The one thing that they have found is what I call — in the marketing and advertising trade there are tune-in ads. So, you’re reading *The Wall Street Journal* — I saw a gentleman here reading the *Journal* earlier — and then you suddenly see a whole page of URLs, places to go on the Net. This is not too dissimilar to listening to the radio that tells you to watch *60 Minutes* on Sunday night. Then you watch “60 Minutes” on Sunday night and they tell you to listen to all-news radio. It’s the same sort of thing.

It’s a very healthy mix that when you’re in print — print seems to be a fantastic promotional tool, not just for any publishing site, but for any site on the Web, whether it’s in an advertisement or if it’s in an editorial — we can track our Web logs any time that we get mentioned or run some advertising, we see our Web logs just spike up, and they’ll stay there for a few days or a few weeks, depending on the intensity of the publication, and then it trails off. Then there’s some pass-along and you can watch the thing go above and beyond the typical baseline of what normally flows through the site. It’s a fun thing to track, actually.

And sometimes, you’re watching the Web log and the thing just spikes and you have no idea why, and it could be because some European publication that — we were in a Dutch publication recently and suddenly, we had a bunch of European visitors, and just by looking at the domain names two weeks later, we could figure — we must have had some exposure that we didn’t know about over there.

So, *The Wall Street Journal* does a pretty nice job of cross- merchandising back and forth. What I think — this is my personal point of view, and anyone who comes along and says that there are hard-and-fast answers to any of this or that what’s true today will most-definitely be true in six months, I wouldn’t believe — but what I believe today is *The Wall Street Journal* has the right idea in terms of pointing people from the site to the print and from the print to the site. These are good links, good ways to set up — not all hyperlinks have to be on the Net. Think of hyperlinks on T-shirts, if you will. It could be on — C-Net, which is a very popular site

on the Net now, has these billboards flying by on 42nd Street in Manhattan now. I look at those as hyperlinks or, as I say, tune-in ads.

Publishers, because they already have a franchise, they already have people built in, they have an audience, can tell that audience places to go and things to do. And if it's a trade book or a trade magazine or a community magazine or whatever, chances are the people who read you are going to want to know all about that. Because, in my opinion, the Web is very vertical place. It's very tribal, and the better you are at identifying the tribe that you're catering to, meeting the needs of that tribe and telling the tribe that you have their needs met at the site and to come and visit it — that complete loop — and the better you are at organizing that loop, the better off you'll be in the long term in getting advertising support for a Web site that again, in my opinion, will probably wind up being mostly there as a vehicle, where advertising is your revenue base.

San Jose Mercury News, let's go there. Now, the *San Jose Merc* is one of those places — we tend to visit it quite often. We're in the business of covering the Internet — we cover the waterfront, so to speak — and the *San Jose Merc* is a place that we go to quite often. Now, when we go in here — now, they have a subscription; they do an interesting tie-in with — if you are a subscriber to their print edition, they only charge you a dollar a month as a value-add for the on-line version, and of course, the print edition is more expensive. If you're not a print — you know, if you don't live in the Valley and you don't subscribe but you want to subscribe on-line, I think it's like \$4.95, and then, what you're allowed to do here is you look through the headlines and you get little abstracts, and then if you want to see the deeper story, then you click on it and you give them your password and you can go inside there. A good model.

It would probably help, I think — I notice that most of their advertising falls at the bottom of the page. Now, I come from a marketing background. If I'm putting up a banner, I want to know that a banner is going to be seen first thing out. So, when somebody hits the site and they say, "Well, we get so many impressions a day," well, that may be so. But the whole page loads and we know that they saw the top part of the screen, but if you have to scroll around to get to the advertising, we're not exactly sure that they did scroll down. We have no way of knowing that.

The advertisers that I typically deal with, they want to see themselves right at the top of the page, so that they're sure when there's a hit on that page, that somebody saw that ad. And usually — and I'll get into this further — do more than just see an ad; they want to see a lot more than an ad, in my opinion. But, if you take a magazine — I'll use my cue cards here for a second — you have the front page of a magazine and then you open it up, the next page is what we call "first cover" in the advertising business. An advertiser pays premium dollar for that. And then "second cover" is here, and then on the back cover, on the back of the book, because of the nature of the print vehicle, an advertiser pays a lot for that.

What I think would be more successful for an advertising-supported publishing site is that the advertising is brought up higher on the Home Page, so that you have a banner and then you have, perhaps, some advertising, then you have a content bar with buttons in it, and then you have some more advertising, more content. Just like you do in a print magazine — you have content all juxtapositioned, from advertising to content.

Now, people will probably disagree with me on this, and as well they should. There is no one right way to do this. But I think that if it were my money, I'd want the ad at the top to make sure that people saw it. Not only would I want the ad at the top, but I would want the ad to be a little bit more contiguous to the content.

Now, what do I mean by that? Just because I read *Wired* magazine doesn't necessarily mean that I'm in the mindset to buy a Volvo that day. The demographics might be right and in the print model, that makes sense. People 25 to 34 reading *Wired* magazine, whatever it is, *Time*

magazine, okay, fine. Demographics in the old style of marketing, in the traditional style, that made sense. I don't know that that makes as much sense on the Web, and I'll give you some examples of how that will differ and how advertising and content really should work more in tandem; not necessarily to muddy the contents so that you don't know whether you're seeing an ad or you're seeing editorial. I'm not saying that. It's more of a hypothesis marketing model: if I'm reading this, I might be interested in that.

And, in fact, we have that now. If you go out and you buy *Computer Shopper*, it's safe to assume that you're going to buy a computer and, therefore, the ads within that magazine are going to be well-placed ads. In fact, I remember a time years ago when I worked in the advertising business, I looked at it demographically and I said, "Let's put a Volvo ad in there." And, Ziff Davis, who owns the magazine, said, "No, no, you can't do that." I said, "Why not?" and they said, "Because people aren't expecting to see that," and they don't — it is, as they say on the Net, off topic. And, right now, a lot of publishing sites and a lot of sites in general — I'm not singling out the publishers — I'm seeing a lot of off-topic advertising. The best example I can think of is: let's say, I'm reading a magazine and I'm in the middle of a story and it says "Turn to page 34 for the rest of the story." And I turn to page 34. Now, on the way there, there are 13 ads, and I have a choice now. I can go finish the article I was reading or I can click on each of those ads and let the ad expand out into its full glory. I tend to doubt that I'm going to click on every one of those ads and wait for them to reveal themselves to me, unless there's something in it for me, and I'll get into what that might be in a little bit.

But, while we're on the *San Jose* site, let's take a look at a source that I use called "NewsHound." NewsHound is a little bit different than publishing on the Web. NewsHound uses e-mail very effectively. And let me take this juncture, this point here, to say that I believe that the Internet is not just one medium; the Internet is a group of media. The Web happens to be one aspect of the Internet. I look at e-mail as a separate medium and it works very well in the Internet — in the Web, and we'll take a look at a Macmillan site that intertwines e-mail and Web together very nicely, because it's conscious that the Web is not everything. It isn't. And e-mail isn't everything. And the other tools of FTP and Gopher, UseNet. There are other aspects of the Internet that are very helpful to know about to a publisher or to anybody for that matter, when you're going out to promote your site, to get the traffic, to draw it in.

But NewsHound — I told you I digress. Going back to NewsHound for a second: NewsHound is a neat service. There are a few on the Web like this or on the Net. NewsHound lets me put in a profile of the kind of news I want and then it delivers it to me. For \$4.95 a month, it says, "Hey, you can have every news article in the universe, if you want it. We'll send it to you." But, that's the reason why you read magazines, is for editing. It's one of the most difficult things to do on the Internet, is to edit.

So, NewsHound and others like it — say you tell us what key words you want to know about and we'll search the Associated Press, we'll search Knight-Ritter, we'll search UPI, we'll search the PR Wire, the Business Wire, Reuters and some other places. And when we find those key words that are high up enough in the story — because you give a selectivity rating so you can have a screen and raise the bar so that — because at first, I said, "Yeah, give me a lot," so I kept the selectivity low and I got inundated with like 50 press releases a day. I couldn't deal with it, so I kept ticking the thing up. I'm up about 90 now, so I get about four really worthwhile, highly-filtered news articles a day through NewsHound. I'm actually paying NewsHound to not receive information. I pay them as much to not get things as I do to get things, which is an interesting concept.

I have a feeling that a few years from now, we're going to look back and think, "God, we did all that manually." And there are people today — you know, we're all bloodshot eyes — our eyes are bloodshot from running around the Internet trying to see everything. It's

impossible to do that. A lot of tools will come on-line, the smart agents — what are those called? — the intelligence agents, right — that will do a lot of this for us. But, some people will go, “I remember the old days when we used to take the wheel ourselves and go for a spin on the Internet.”

W: Are you interruptible?

Larry Chase: Am I interruptible? Can you hold it? Okay. Let's go to *USA Today*. Usually, in real life, I am interruptible.

M: [inaudible]

Larry Chase: Say again, sir?

M: [inaudible]

Larry Chase: This is not real life; this is the Internet. I have no life. I suspect most people in this room have no lives anymore. If you're on the Internet, you probably gave your life up when you — “Abandon all hope, ye who enter here.”

USA Today, I got my copy this morning. I assume probably just about everybody did. Now, why would I read *USA Today* over there or on the screen over here, as opposed to in my hotel room? That's a good question. I'm not sure I have an answer. *USA Today* is sort of like a headline service. I want to get a top-line read of what's going on internationally, the region that I'm traveling in, back home, sports, weather, stuff like that. They have nice graphics, but I'm trying to figure out what they're going to ask for a subscription to this. I believe they're going to ask something like \$12 or \$13 a month, and I'm not quite sure what will be accomplished. If it was a database like Lexis or Nexis or Dow-Jones or Reuters and it was a huge, historical database, and I was a lawyer and I needed to go find a precedent piece of law from 1974 or something, I'd pay good money to go and retrieve that information.

But, for top-line information, to me, the newspaper seems a little bit more appropriate for it. It's portable, I can read it on the bus over here, I can give it to him, I can cut things out; I see a URL, I can rip it out or whatever and put it in my wallet and take it home and so forth. Why would I want to search *USA Today*? I'm not exactly sure. I think it's also a little bit overpriced.

I also think this will happen, and I'll probably be proven wrong — God knows, I have been in the past — but, I think that what will happen is the subscription will filter a lot of people out immediately. Once you filter a lot of people out, then obviously less people come to your site. You have fewer hits, whatever they are. You have lower traffic. If you have lower traffic, you're going to have a harder time selling advertisers on advertising in that medium.

If I were *USA Today*, I think I would make it free and it would be a fantastic — I would have a travel center and I would go out and get American Express and Hilton Hotels or whatever, and just leverage the heck out of that. Because chances are, people who read this — and conferences, too. Usually, I see it when I'm at these conferences and probably you do, too. So, it would be a wonderful place to use as an anchor for — *USA Today* on trade shows, *USA Today* on travel tips or whatever. But, I would do it for free and use that brand name that the Net has to build large traffic and sell that traffic to the advertiser. It'll be interesting to see over the next 6 to 12 months how this model works.

Now, *San Jose Mercury News*, you notice, that was also subscription, but that was a little different. That was trade news, and for trade news, I might be apt to pay a little bit more than

that or I might be more inclined to pay something — something. Even at that, it's less than \$12.95. So, keep an eye on this. In your folders, you should have an itinerary of most of these Web sites that we're visiting, so hold onto that, if you want, and when you go home, you can keep track of these sites, because by the time you get home — if all of these people are playing their cards right, by the time you get home, all of these sites will have changed.

And that's another thing that parenthetically I'll bring up here, and that is, as I say, you can be Mobil Oil, you can be the *New York Times*, if you're on the Web, you just got into the publishing business, like it or not. And for the same reason that I wouldn't go to the newsstand to buy the same issue of *Newsweek* last week, you can't expect people, of course, to come back to see the same information that you had last week.

A lot of times we get — one of the services that we offer the agency is what we call this — what do we call it? I forgot. It's volleys of messages that go out and go, "Hear ye, Hear ye, come to this Web site" for whatever reason that happens to be, the reason they joined that Web site. A lot of times, people ask, "Will you do some messaging for us, you know, send out some of those volleys and tell people we're here again?" And I'll say, — to use a publishing term — "What's the news peg?" And they'll say, "What do you mean?" And I'll say, "Well, what has changed in the site? What is different?" "We have a sound bite of the CEO now." And I'll say, "Well, I don't honestly think that if I go out on your behalf and start propagating messages — you know, come to this Web site, there's a new sound bite of the CEO, I don't think that that's going to draw in a lot of traffic." Therefore, you have to think a little bit more like an event marketer or like a newspaper even, and say, "Well, what's going to draw the audience? What kind of headlines, what kind of information will draw this audience in?"

So that when you do send out these volleys of information to other — you know, to Yahoo or to WebCrawler or to parts of the UseNet that may specifically talk to your particular market niche, you want to have an event in mind or a piece of information, high-value content; a novelty sometimes works. You know, people like downloading screen savers or games or something. And, of course, there's always the good, old financial incentive. Come to this Web site and save \$5 on subscribing to the hard copy of the *Wall Street Journal* or what have you.

But there should be some reason, some draw. Because, again, if we go back to the lilypads, why should I come to your Web site when I can go to the Library of Congress, when I can go to the *New York Times* or the *San Jose Mercury News* or Newslink. What is the reason? You've got to think about me, the user. You have to be a user and look at your own patterns to figure out what's the draw.

I'm doing a seminar tomorrow, the first one I'll do in a tent, which is kind of interesting. My great-grandfather was a promoter, so I've never delivered in a tent before. But there's got to be some kind of attraction, some main attraction. And in the case of publishing, it's content. That's why publishers, I think, have the opportunity of a lifetime. They're sitting on a pile of content. The question is how are you going to market that pile of content; how are you going to repurpose it? You've already got it. It's sort of like airplane seats. If an airplane flies empty or half-empty, you might as well sell the seats at half-price. That's why there's standby. The same thing here. You've got news. News is like bananas; it doesn't stay around forever. Nobody eats yesterday's bananas, or something like that.

So, you might as well repurpose it and put it up on the Web. Really, it's not that expensive. The cost of it is constantly coming down, and if you can get either extra revenue for advertisers that you now don't have or probably — and more probably, I think — you will get advertisers that you have now in your existing media, your existing print vehicles, and migrate them over to the Web, and that way, I think publishers earn the cat-bird seat. Publishers more so than ad agencies, because publishers know how to deal with content; ad agencies, much less so.

Now, ad agencies are supposed to bring marketing prowess to this, and I haven't seen a lot of marketing prowess being brought to this medium from ad agencies. With publishers, they're used to dealing with content, used to serving it up, and they know what draws. So, if you add a little bit more marketing to that mix, I think you are in a very good position to grab a piece of the marketplace.

Don't try to grab everything. Some people ask, "How many people are on the Internet?" And I have two answers: "I don't know" and "I really don't care." I'm not trying to market to everybody on the Internet. If I were marketing to everybody on the Internet, I'd be doing something wrong. I need to carve out a niche or carve out, perhaps, two or three niches, and try to cross-purpose content across those two or three niches.

That's more of what it's about, making money off of little ponds of markets rather than trying to sell one thing to everybody. This is a different medium and people aren't expecting that, and that's probably why those lawyers got so roundly flamed a couple of years ago. You know, Kantor & Siegel, when they sent out — there you were in a UseNet forum reading about tropical fish and then you suddenly got "Get your green card before June 30th, Kantor & Siegel," or whatever. It was off topic. It was rude. People don't like that. They won't accept it. I'm getting junk e-mail now. I'm not a proponent of that. I look at it and as soon as I see it doesn't say my name and "Dear Larry" or "Mr. Chase" or whatever, as soon as I see it's just a broadcast piece of mail sent to a thousand other people, I kill it. There's too much information out there now. We've gone from not enough to too much. Some people say by the end of the year, there will be 500,000 Web sites; that's a lot of information.

How are you going to attract people? A, how are you going to attract them, and then B, how are you going to let them know? And that's where you have to set up a marketing plan that says, hey, this specific group, we've got content that would be of interest to you. If you're reading this UseNet group on tropical fish, Hartz Mountain has all about fish care, or download a screen saver from Hartz Mountain or learn how to breed parakeets in your spare time, whatever. But there, at least, it's on topic. It's also an example of using UseNet — like AOL has 400 or 500 areas of specific interest, UseNet has something in excess of 15,000 or 16,000 now. So, you're apt to find niche audiences.

And after all, that's what much of publishing is about, is niche marketing, particularly book publishing. You have to find niche audiences in your UseNet group. If you search hard enough, and then if it's on topic and appropriately done and you lurk and you follow the UseNet group and the threads and how people introduce themselves, and so forth, if it's appropriate, then you can put a message out there that's appropriately worded and it's not too promotional for the information and for the benefit of the readers — that is good Netiquette. Because that is information that they probably want to know about.

Let me go to something that's overtly commercial, and that is classifieds. It's another part of publishing that we haven't talked about yet. A site called "career mosaic." There are a few sites out there that deal with publishing of classified advertising. This site is produced by a gentleman named Mark Harning at Bernard Hodis Advertising.

Now, Bernard Hodis is a recruitment ad agency, and they are the largest buyers of classified space in the country, because they place all these classified ads. And what's nice about this particular thing is Mark went up about the same time I did, a couple of years ago, and at that point, he had a few companies that were looking to hire typically — most of them were in Silicon Valley — looking to hire programmers and so forth. It's gone further out than that now into other fields: public relations, marketing, graphics and so forth and so on, as the industry of the Internet is expanding rapidly. But, this is an example of commercial information, purely commercial paid information that people will go and look at, just like they do today in

the newspaper. They'll go in the back in the classifieds and look to buy or sell a used car or look for a job or look to sell a house. It's the same sort of thing.

The Internet is a very good indexing medium. I'm sure everybody in this room has heard the name *Yahoo*. It's one of the biggest indexes on the Internet. It's a wonderful way to look up jobs or mass amounts of information. On this site, you could say, "I'm looking for a job for a copywriter in the Northeast in medical," and you could see if there are any companies out there looking for a medical writer willing to pay between \$45,000 and \$60,000 dollars. Oh, there's one in New Hampshire. It's for this sort of thing that people will seek out commercial messages.

We'll go to the next one, which is the deck-direct catalog. It's a different kind of publishing model. Again, it's commercial information. Now, you get catalogs every day in the mail. I tend to throw a lot of them away, unless I'm looking for something at that particular time. We just moved offices, and I happened to get a catalog that talked about local area networks and computer equipment. By pure accident, the people who sent me that catalog got me to look through their pages. But, the Net is a self-directed place. I also went out on the Net looking for specific pieces of furniture and things for the office, because I needed that commercial information, so the Net is also, in addition to classifieds as a commercial content, catalogs also serve very well for commercial content, for a number of reasons.

Let's take, for example, let's say, there's a laptop that they're out of stock in. No more laptop. Now, in the print catalog, that's too bad, because I'm going to have a lot of people calling me on my 800-number asking for that laptop, so I just paid for an inbound WATS line, only to tell them, "I'm sorry, we're out of that laptop." If you're publishing on the Web and you run out of those laptops, you just go in there and you take it out. People stop calling, for that laptop, anyway.

The other interesting thing about this particular catalog, it was created by a company called Convergent Media Systems. And what I like about this is that it took the assembly line of a catalog and it realizes, you know, if you're going to make a catalog for the Internet, you might make one for CD-ROM as well, and then, of course, you have the print one, too. So now you've got three assembly lines. Well, the catalog here that you're looking at also appears in print and also appears in CD-ROM. Now, it's not exactly the same. The one in print, of course, has better graphics and the CD-ROM one has moving images. This one, of course, has lighter graphics so that it doesn't take all day for the graphic to come up on the Internet, if you want a 14.4 or a 28.8 line.

But the point is that you can build an architecture of a catalog, pour the information in and then just tweak it three different ways, depending on the channel, the sales channel, whether it's a magazine for CD-ROM or what have you, that allows you to collapse the assembly process down significantly. That's why I like that and why I showed it to you now.

Let's go over and talk about magazines, now that we've covered newspapers and paid-for advertising. *Money* magazine, pretty popular site. Pathfinder itself is extremely popular. In fact, I think Bruce Judson of Time-Warner is talking here at Internet World. They've had a rather successful launch with that. They've got a lot of advertisers. Again, I notice the advertising is very often at the bottom of the page. I respect the content a lot here. There are things that I like in *Fortune* magazine, if I want to go back — or in *Money* magazine, if I remember that they had an article about estate planning, but I can't remember if it was one issue or two issues ago, I can come here and I can find it pretty fast.

M: [inaudible]

Larry Chase: There's a lot of advertising. You want to go in? And I'd probably say, "No, not necessarily. Thank you. I think I'll continue reading content." I have the same constructive advice here, that I think the content needs to be a little bit more enveloped and contiguous with the advertising.

For example, if I was looking for that article about estate planning, I think it's Northwestern Life Insurance Company that actually has an on-line calculator that — a longevity calculator that will tell you about how long you'll live, which is kind of a scary thought, actually. But, if they sponsored that article, that would be a nice synergy. That would be something that if I were looking at that content, I might be interested in using that calculator, and then if I'm using that calculator, well, maybe I am interested in a life insurance policy, or maybe I realize I don't have enough, or, I'm going to die too soon. Maybe I should take out life insurance now. So, these are the synergistic kinds of juxtapositions that I think can be explored.

But when you have a place called "Marketplace" — and I've seen these a lot in different sites. We had a media buy with a very large publisher on the Internet that has a place called Marketplace, and they rotate the ad so that they can get a lot of advertisers, and they put it in rotation. So, one week we're on the Home Page, the next week we're in the traveling section, and then the week after that, we're in this thing called Marketplace. We do all this tracking, so that any of the hits, any of the traffic that's coming from that site, it comes in a certain door. And like in the movies in the old days where the guy would sit there with a clicker counting how many people would go in, we can see how successful or unsuccessful that advertising is.

Every time they put us in that area called Marketplace, the hits just fell off a cliff. When we were on the Home Page, it was fine. We'd get hundreds of people a day coming from that site, because we were sponsoring a traveling site and the sponsor happened to be Hotel Discount, so that made good synergistic sense. But, every time they put us into the Marketplace, we called it the closet, because as soon as you're in the closet, how many people are really going to ask to see more advertising, unless they're given an incentive up front, like there's a financial incentive or there's good content incentive. But just to simply click on something that says Marketplace — I mean, I do it because I want to see who's marketing on the Internet, but I'm not sure, I'm not convinced that a lot of other people are going to do that.

Now, what's also good about the site from Time-Warner here with *Money* magazine and so forth is that it's part of a larger structure called "Pathfinder," and there is that model that works very neatly where you can — just like they do with their traditional publications — you can buy *Sports Illustrated* and then buy *People* magazine and *Money* magazine, and maybe they'll give you a volume discount, and that's a good way to cross-merchandise. Or maybe they've got deals going where if you pay us full rate card on the print edition, we'll give you 30% off on the interactive edition.

Now, they're not going to share that information with me, but if you're an advertiser and they're trying to get more advertising up on the Web and they see it as possibly a way to bring you into the publication and add more value that *Newsweek* — you know, let's say it's *Time* magazine. Now, you happen to be selling computers or modems or whatever. It doesn't have to be hi-tech; it could be anything. *Newsweek* is not yet up on the Net, no. *Time* magazine will give you exposure on the Net for the same amount of money. You'll get this many more impressions. They'll be electronic impressions rather than page impressions, but that might be better for you.

So, again, it's a competitive edge that they've garnered now in their particular niche, which is pretty large, of news magazines. They're able to sell through something that they're arch-rival, *Newsweek*, in this particular case, cannot yet promise them. So, it's also a good cross-selling tactic for the publication, from a sales and marketing point of view.

Let's go to *Epicurious*. *Epicurious* is an interesting magazine that is sort of a hybrid. It has a little bit more of an attitude, because it's based on the Net and it's not a direct descendent of one magazine. So, we've taken publications from the print universe and looked at how they manifested themselves on the Internet. Now we're starting to look at things that are purely created on and for the Internet, very often, with editorial that was originally intended for print. *Epicurious* is a very nice area that offers some nice, deep content in the area of food and life enjoyment, along those lines. There's not a lot of advertising on the site yet, but you have to give them credit for putting the content up first. They're sinking a lot of money into establishing an audience and then going out and getting the advertisers.

[Tape change]

Larry Chase: ...site for a client that already has advertising. Most clients want to say how many people do you have? Are they my kind of people? When you first launch a site, you don't know how many people you have. You don't know exactly what they are, so chances are, you're going to launch and you're going to be out there for a little while without a lot of advertising support, and that's what we call an investment of time and money. And that's pretty much what we're seeing here.

There are some others — *Popular Mechanics*, again, has very nice, glitzy graphics, but not a lot of advertising. We've seen some magazines come out of the box or out of — going public, launching and they'll ask for phenomenal amounts of money. I remember one magazine asked \$10,000.00 a month, and they had the slickest media kit. It was really dazzling, and the content was really rich. I must say, it was really exactly what was right for my client at the time. And then I said, "How many people are you getting?" and they said, "We're not sure." And I said, "But you're asking me to spend \$10,000.00 of my client's money against an audience that you're not sure is there yet?" And they said, "Yes, but you'll be a charter advertiser." And I said, "Well, I think we'll wait. We'll wait till you fill that audience."

And I found myself asking exactly the same questions that an advertiser asks a traditional publisher: What are you doing to promote the magazine; how many people know about it, what's the circulation? How many people come in every week; how many people come in every month; what's your promotion budget; how are you going to drive traffic through? You may go up on the launch and you announce in *Yahoo*, you announce in *Web Crawler* and in all the other industries and so forth. How long is that good for? That's good for a couple of weeks, but what are you going to do for an encore? How are you going to get these people to come back?

And that is the acid test question: How are you going to get these people to come back? One of the things that you can do to that end is to send out e-mail reminders, which is what we do on our side. I'll show you in a minute. And it reminds people — some people actually want to be reminded to come back, because it's an outbound kind of medium, where people, surfers, viewers, readers — call them what you will — they have the driving stick; they're in control, but they may forget about you. I mean, after all, if we're going to have a half a million sites by the end of the year, there's a lot to think about.

So when they're on your site, you may want to say, would you like to be reminded when this site changes, would you like to know about it? On our site, we've noticed that 80% of the people — it defaults to no, because we don't want to breathe on anybody — but 80% of the people take that default of no and turn it into a yes. So, every time we put out a new edition of *WDFM*, a few thousand people know about it, they come back, it hits the server log, we're able to collect that data, turn around to advertisers and say we're holding our circulation or, more often than not, our circulation is increasing because we have a built-in base of people and more and more are coming in because of the promotion.

Frankly, we're taking just about all of the money from our advertisers and pouring it right back into promotion, just to build up market share. And we're probably going to do that for a good long while, but I also have other ulterior motives for publishing that publication. I never intended to really make a lot of money on it, so I don't really mind taking that revenue that I'm getting off that content and pushing it back into promotional advertising or, again, as I called it earlier, tune-in ads.

But again, I digress, so let me go back. We were on *Epicurious*. Not a lot of advertising there yet, stay tuned.

Let's go to e-zines. I mentioned Newslink earlier, which points you to just about every major news service on the Internet. By the way, just as an aside, nothing has everything. I don't care how good they are, it's impossible to know everything, so if I say that Newslink is good for having — and you're in the news business, you're with Associated Press, or what have you, or Knight-Ritter, or whatever, *New York Times*, Newslink is a good thing to have. But if you see another one that's kind of like it, I would bookmark it, because it may have a couple of areas that Newslink doesn't have, and you should collect those — pointers to pointers, as some people call them — just so you have a good comprehensive view of your particular universe.

The Web itself and the Internet at large has gotten really too big for any one person or company to get their arms around. A year ago, you really could. I remember when we went up a couple of years ago, we didn't have a lot to put up. We had a Home Page and some descriptive text, but everybody, they ran over to see it, because there wasn't much else to see. When Pizza Hut went up, Pizza Hut spent about, I think, less than \$20,000.00 to put that original site up. It sat on a Pentium box, but they got a million dollars worth of play on it. The GE catalog, 1,300 pages of plastics. You know, it made the NBC Evening News. Today, that's not going to happen. You have to do something else. Going up is no longer newsworthy.

As I say, when I went up, people came over just for the novelty of seeing what an on-line ad agency looked like. Today, every day there's another ad agency on the Web. It's not news. It's like saying, J. Walter Thompson bought a fax machine today, or something like that. Why are you telling me this? So what?

That's why I say the bar keeps getting higher and higher for value-added content, particularly in publishing, because information is that core business. You have to give something away. Notice, when we went to the *San Jose Mercury News*, they had something there, even for people who didn't pay anything, and I think that's important. The other subscription services do the same thing, for the most part. They'll give you some stuff, almost as if to say thank you for stopping by, but it's very un-Netlike to say, "Restricted, there's nothing here for you; go away." There should be something that you should offer to somebody who may or may not come by. After all, it's public relations, and if you've got the content, err on the side of giving something away — that's what I would say to you.

Let's go to C-Net. We're now going into the land of zines. What is a zine? What is an e-zine? Everybody has a different description, a different definition of this. I would say that a zine is basically an electronic version or an electronic magazine. It may not even be a version of a print magazine. Very often, it is not, in fact. C-Net is a type of zine. It happens to be a very big zine, because every week they have a half-hour hyperlink called a television show, and it airs on the Sci-Fi Channel and USA Network and some syndicated stations around the country. Everything that they talk about on the TV show is covered in more detail on the Web site. And, again, it's a great example of a cross-promotional tie-in.

So, you go to the Web site and it refers to the TV show, it even has video clips of the TV show. You watch the TV show and there are always URLs going along the bottom of the screen of where specifically on the site to go to get more information, which is one very good reason why you really do want to think about publishing on the Web. If you're buying space —

you know, newsprint is expensive, cyberspace is not. You can elaborate forever on whatever it is you want to talk about, whether it's tropical fish or science fiction or what have you. There's always more information for those who want it available on the C-Net site.

So, C-Net is a type of zine. It's sort of a hybrid TV zine, if you will. It's a good model to work from, if you have a television network in place and a video crew. They do a very interesting thing on the C-Net. They have a video camera that is fixed on the studio, and it changes; every minute there's a new picture. So when the TV show is live, you can see these sort of herky-jerky-looking pictures of John Devorak or whomever is giving a review of whatever Netscape product there is or whatever. You can actually see the show live on the Web site at one frame a minute, or something like that. I looked at it last night and, of course, the studio was empty. It was the middle of the night, but there it was. That's a form of publishing. It's not just textual information. It can be very much graphical information, as Bill Gates can tell you. He just bought the Bettman Archive, and you can bet that that'll probably be made available at some point electronically, as well.

While we're on the subject of zines, let's go to *Tripod*. *Tripod* is a lesser-known zine. It's sort of like a *Wired* or a *Word* zine. *Wired* has its magazine equivalent and its print equivalent. *Tripod*, there is no print equivalent for *Tripod*. This is it. This is aimed at 25, 30, 35-year-olds. Very popular site with the people in my office. I asked them where do you go in your spare time. They like to go here. I don't necessarily frequent this, but then again, this is a different niche audience. This is aimed at them. It has nothing to do with me. They happen to think very highly of this site, so at some point, it's not unthinkable if this becomes popular enough that this goes into print. And that's a point I wish to make here, is that the Web is a very interesting tool for test marketing.

Let's go to *WDFM*, the next one. *Web Digest for Marketers* started off as a zine. The history of this is interesting. I'll share it with you. Originally, we were going to offer it as an e-mail subscription and charge \$125.00 a year for it and, in fact, we put out press releases and advertising that said just that. And we were getting checks in and we were quite happy about that. And then we realized, you know, in about a year's time, people are going to be offering this information for free, just to garner the audience, just to get that audience share, so we don't want to be in the position of having to charge for that information, as I said earlier.

So, let's just eat the investment now, build the market share, invest in some advertising saying, okay, forget it, it's free now. We were charging \$125.00, now it's free. That worked very well. So well, in fact, that we've now syndicated it and it's in print. You can read it in *DM News* and it is soon to be in some other publications, both here and in Europe. What we learned from this — and we had no idea that this would happen; this was not in the business plan — what we learned from this is that you can test-market something on the Internet fairly inexpensively. All you have to do is write it and some pretty basic graphics. Nothing very complicated about the graphics you're looking at there. So, we found out that there was a good, solid, loyal audience that came back repeatedly for this.

And then some other magazines and newspapers started approaching us about it and started to say, "Well, how about if we syndicate it?" And we said, "All right; that sounds good." So we have various syndications. Some of them are revenue-sharing; some of them are a swap of space for content for advertising. It works all different ways, both on the Web and other sites.

That's another point I want to make here. In the coming weeks, this will not be the only site where you see *WDFM*. Very much in the same way that you see "Star Trek" on different stations in different TV markets, the same thing will apply here. I'll license this content to other people. They'll either pay me outright for it and then get their own sponsors, or we'll have a

shared revenue model or point back to each other. But the syndication model, I think, is one that you're going to see a lot of.

And, in fact, if you go to the Meckler site, you see that — I had a very good example of that with *Interactive Age* and the *New York Times*, but then they took it away, so I can't show it to you. But for a while the *New York Times Computer Daily*, you could go to the *New York Times* site or, if you were so inclined and wanted the million people a month that happens to go to the CMP Server to read *Interactive Age* or *Net Guide* or whatever, you could go to that server and you'd go, "Oh, I didn't even know the *New York Times* had a *Computer Daily*," and you could read it on that site. It doesn't really matter what site.

You don't have to be necessarily so proprietary or protective that all roads must lead to the same site. It doesn't matter much to me whether I'm getting ad revenue off this site or off of a site in Europe that's drawing an entirely different crowd or the same crowd. I'm still getting a piece of that and that's fine with me. If somebody else wants to invest in the promotion of it and so forth, it's a good deal for them because they get content at a very inexpensive cost and then they have something to sell against. I think we'll probably see a lot more syndication models on and off the Web. This is one lesson that we learned from this.

And the other thing is that it's a good test vehicle, so that if it works, you can pull it backwards into print, which is what we've done in a couple of trade magazines that are right now aimed at marketers, but pretty soon we'll be in a few other Internet-specific magazines, as well.

The other thing I wanted to point out about the site here, is that you have different — notice, the banners all come up. You don't have to scroll anywhere. The advertising is there, so USA Data, EDS and Lotus know that every time somebody hits that page, their banner is seen.

But in my mind, to be frank with you, that's not enough. Where we're going now, where people don't have much time to arbitrarily click around and wait for graphics to load, you have to give them a pretty good reason to click on that banner.

So let's say, if you click on — if you're reading *Web Digest For Marketers*, it's a fairly safe assumption that you're somewhere in the food chain of putting up a marketing site on the Web. It's a pretty good safe assumption. If that's the case, then you may be interested in what USA Data has to offer. I'll give you something for free that you would otherwise pay for if you click here, and that's why it says "free samples of how we slice and dice data." And what they chose to do here was give you market segmentation of long-distance telephone carriers. They figure, well, people that are on the Net are probably bandwidth sensitive, so there's a good reason for marketers to look at that, because marketers are always interested in research information and how to slice and carve data for their own purposes, and this might be something that they want to take a look at. It's a good reason for them to not just advertise with us.

You know, if they just dump to the Home Page, the USA Data's Home Page, you would probably lose your prospect. You go, "Uh- huh, okay. Another company that offers research data on the Web. That's very interesting. Okay, let me go back to WDFM that I was already reading." But here, they're drawing you further and further in and showing you — strutting their stuff, basically, and showing you what they can do.

We ultimately want people — and I think everybody or most everybody should basically have people come to their site as much for the content as for the advertising. And I know that might sound a little bit ludicrous, but I mean it. The advertising is going to have to be relevant. We work under a basic premise that there is commercial information that people want, and they go for it every day, and they even ask for it, as in the case of classifieds or catalogs or what have you. There is information that people actually want. If you can figure out what kind of information that they would be interested in and give it to them and give it away for free, then you probably have somebody who'll say, "I think I'm going to come back to that site; I think I

want to see what else this person can offer me in two weeks —” if you’re lucky. Or you’ll have to send them an e-mail reminder.

And in fact, people who sign our guest log, we go in and say, do you want us to remind you, and most of them, as I say, they say yes. So people come back to see not only the new content when there’s a new edition, but they also come back to see the new advertising.

In fact, we’re opening up an area that is special, that are aimed specifically at marketers, so that if you’re into marketing, these will be like, you know, get an extra 10,000 impressions if you advertise on Riddler, if you click here, that kind of incentive type of marketing. I think it’s that kind of direction that the Web will take, that value-added reason to click here. I think just have a beer banner in the middle of text, I just don’t — right now, it’s like the 1950s. You look at advertising in the 1950s and it looks rather quaint. You know, you see little Old Gold boxes dancing around the vaudeville stage. Well, that’s cute; it’s amusing, and people sat around every night and they watched that for 60-second strips at a time. But then commercials got to be 30 seconds and then 15 seconds and then 10 seconds. Now you’ve got 3-second rolling billboard tags. People in the early days would look to see what the AT&T logo looks like on-line or what Volvo looks like on-line, but they’ll only do that once or twice, I think. After that, they’re going to want to have a real good reason to click on that. Otherwise, I think you lose them. So that’s WDFM.

The other side of this is — oh, did we show that e-zine list? Okay. There’s a list, a very comprehensive list of e-zines. Just like there’s Newslink to point you to a lot of different news sources. Again, it’s pretty comprehensive, nothing is complete because as we speak, there’s probably three new e-zines going up, so maybe tomorrow they’ll be as comprehensive as they should be today. But it’s just impossible to know everything that’s going on out there.

There are other different kinds of zines that I want to talk about. Not all zines are created equal; not all of them have graphics; not all of them are even on the Web. There are a couple that I want to talk about, and it’s hard to really surf them, because they’re not on the Web, so let me just verbalize what they are. There’s one, in particular, that I like. It’s called *Net Surfer Digest*. Now, I get a lot of magazines via e-mail, but this one comes in HTML. It actually comes all scripted, so that I can open it up in Netscape and when it talks about a site review, then I go, “Oh, that’s an interesting site. I’ll click on it.” And then it goes to that site. That’s a neat trick. It’s not hi-tech, but somebody had an idea that this was do-able. With the technology that’s out here now, we can just send them — and they give you the choice of you can have it as straight text, just like your e-mail, or you can have it as hyperlinked and open it up in Netscape or in Mosaic or Warp or whatever it is that you use, MSN, and the reader will read the hypertext. If you’re not on-line, you can click on it, it’ll pick up the modem and dial you out and it’ll take you right to the site that’s being talked about. There are other zines that are purely textual. WDFM, *Telecom Digest*, there’s thousand and thousands of these. Impossible to know how many, because some of them aren’t even public.

There are zines that go out as purely textual that are very, very down in the groove. There’s a gentleman here in the audience who puts one out from the IEEE, International Engineers. Not everyone in this room is going to be interested in it. Not everyone in this room should be interested in it. That’s the nature of the Internet, that it’s going to be a niche market. His magazine goes out to about 50,000 people. Now, does he care how big the Internet is? I don’t think so. He just knows 50,000 people get this newsletter once a week — once every other week. That’s a pretty respectable population, especially when you stop to consider that the cost of distribution is nothing. That’s pretty good. That’s a fair amount of influence.

Now, the downside of that is there are no graphics, if there is in fact a downside. Some people would prefer less graphics. And it’s not particularly pretty to look at, but it is effective and there’s one thing you can say about e-mail, it’s ubiquitous. Whether you’re on Prodigy,

CompuServe, AOL, Delphi, NL-Net, wherever you happen to be around the world, chances are you're not too far from e-mail. As far as the WorldWide Web, I don't know. I hear figures from 7 to 12 million. Frankly, I don't know what to believe anymore. I don't know that they're ever going to have hard-and-fast figures on that. I just don't know that the medium will allow for it, frankly.

But saying that you have 50,000 people reading your newsletter — I'd say that's pretty respectable. Same thing with the Electronic Newsstand. Jeffrey Dearth up here in Cambridge has the Electronic Newsstand — 200,000 people visit him every day. Does Jeffrey Dearth care whether there are 30 million people on the Internet or 40 million people or 10 million people? I don't think Jeffrey cares. He doesn't have to. He knows that he gets 200,000 people a day looking at subscriptions in the Electronic Newsstand, and he sells subscriptions on there. Then he had the prescience to realize, "Wait a minute — not only can I sell subscriptions here, but people who come to look at old editions of *Internet World* or of *Marketing Tools* magazine or *American Demographics* or whatever, people who come here looking for that, maybe they should also have some advertiser support there." So, he found himself a whole new revenue stream. When he migrated his site from his Gopher site to the WorldWide Web, he found a whole new stream of ad revenue that he didn't have before, because it was graphic.

Let's see, what else do we have here? Books. Let's go to books. Let's go to the video tape. I know we have a few book publishers in the audience here. Is now a good time? Why don't we take a five-minute stretch break and then we'll do books and finish this part and we'll take some questions, and then I'll be interruptible. Thank you.

I know we have a few book publishers in the audience here —

M: [inaudible]

Larry Chase: Yeah. I mean, that's me. That's what I like.

M: [inaudible]

Larry Chase: What was on the bottom?

M: [inaudible]

Larry Chase: Oh, on WDFM?

M: [inaudible]

Larry Chase: Well, see, but that's what I'm saying. On many of the Web pages, they are at the bottom and you have to scroll down.

M: [inaudible]

Larry Chase: I can't say whether they do or they don't. All I'm saying is that you don't have a good handle on whether they see it or not, because you have no way of knowing whether they did scroll down or not. You can't track that. And as an advertiser, I want to know. You see what I'm saying? You can't tell me, this page got 200,000 impressions. All that you know is the top half of that page got 200,000 impressions. You can't tell me with any certainty that you can scroll down and everybody else saw that ad at the bottom of the page. That was my point on that.

M: [inaudible]

Larry Chase: It's a learning process. I know, because advertisers ask me these questions. They go, "Well, I have to scroll down to get my whole banner."

M: [inaudible]

Larry Chase: I haven't had one complaint about it. Exactly, exactly. If you're doing your homework right, then it's information that they're going to want anyway. You know, if it's a financial incentive, whatever, they shouldn't mind it. It should be appropriate.

Okay. Give it another minute for people to settle in and then we'll get back to publishing, already in progress.

Some very interesting questions and I'll open the room up to questions in a few minutes. Very interesting questions about sponsorship and what to offer advertisers, how to pitch advertisers your content, and also a particularly interesting question about syndication and the tension that's between the immediacy of the Net. Do you hold your content back for the print publication that wants to print it and so forth. Let me go back to books first, though. We'll finish up with books.

Book publishers are coming on the Net in droves, as you probably know. I'd like to stop by the Macmillan site and show you something there. Interesting use of e-mail there. It's the super-information library, and one thing that we like about this site is you go in and, rightfully so, I think, it shows a bunch of different areas of trade, trade books that are available, or trade books that you can find out about when Macmillan publishes them and then, indeed, you can go in.

For example, I went in the last seminar I did and I clicked off books about on-line communications and on-line marketing, and probably once every week or once every two weeks, I get what's called a "bot." It's a robot and it's a robotic piece of e-mail. It's one of the few robotic pieces of e-mail I actually read that says, as per your request, Mr. Chase, Macmillan has just published *The Ultimate Guide to Marketing on the Internet*, or whatever it is. But based on my behest, my inquiry of a few months ago, it kicks back books of interest to me.

The question that I have for book publishers is this: For an end-user, what do you expect an end-user to do with a publishing site? And I think this is something that book publishers are grappling with, whether it's Macmillan or if we go over to the Bantam-Doubleday-Dell site, which is a pretty nice site, as far as book publishing goes. You know, you can get tours of authors and book-signings around the country and so forth and so on, and maybe on occasion, you can get the first thousand words of a book.

There's a site out there called "Dial-a-Book." It offers you the first thousand words of any given text in its library, and then if you like it, then you can buy it right there. In fact, from Dial-a-Book, if you like it that much, you can buy the whole book and download it all complete; you know, round-turn fulfillment, as they say.

But here on the Bantam-Doubleday-Dell site, it's a nice site, nice graphics. I think they did a fine job with it. But an end-user — what is an end-user going to do? I mean, think about it. When you go and you buy a book, do you go to Bantam-Doubleday-Dell; do you go to McGraw-Hill; do you go to the Macmillan Bookstore? No. You go to Barnes & Noble; you go to Walden Books or Paperback Booksmith or whatever. But you don't typically go to the publisher for a given book, unless it's a trade publisher or a specialist, sci-fi publisher, or something like that, that is so specialized that only they will have what you're looking for or they are one of the few publishers that have what you're looking for. I think this is a problem for many publishers.

I think the way that they might want to solve that is to put up their retail divisions. Right now, what they have up mostly are the corporate sites. But Bantam-Doubleday-Dell has one of the largest book clubs in America. Where is it? It should be up. Book-of-the-Month Club would do very well to be up. Cross-promotions — and again, this is more of a marketing thing, but if, say, Book-of-the-Month Club is up, then maybe Bantam-Doubleday-Dell says, “We see you’re in this science fiction area here. We have a special on the new Frederick Poll book or the unfinished Asimov or something. Click here or point this way and we’ll come to the B-D-D site and we’ll give you the first thousand words free,” or something. This begins to make sense to me, because this is within the buying habits of what people do naturally.

And while I’m on buying habits, let me speak to that a little bit. I can’t tell you how many times I’ve told people not to go up on the Internet. A lot of times, people are undercapitalized or they just have the wrong idea. They go up and they put their site together and then they say, well, we did that. But it is publishing, whether you’re in the vertical field of publishing or not. You have to refresh that site constantly and you have to budget, not only for the refreshment of that content, but then you also have to budget for the promotion of that content and going out to the appropriate places on the Net — on the Web, excuse me, I need to differentiate — places on the Web, places on UseNet, set up your e-mailing lists, and so forth and so on. I liken this medium more towards direct response and sales promotion than I do towards brand advertising. And I’ve done both. I grew up in the brand advertising universe.

A gentleman before came and asked me during the break here, well, we have the right demographics for someone like American Express. Well, that’s good, but the problem out there is that probably 300,000 other sites also have the right — after all, probably most of the Web has — if you’re on the Web, it’s quite a filter already. It means you have a modem, it means you have a computer, it means you’re somewhat literate, you’re probably making some kind of income or you’re a student, which means you have probably a certain amount of educational level. A lot of predeterminations have already been made, given the fact that you’re already up and on the Web itself. Now, going to American Express, for that gentleman, he’s got to compete with then 200,000, 300,000, 400,000 other sites. It’s better for him to go to American Express with a specific marketing plan.

Now, in this particular case, he has parents and kids. Now, my reaction back was what you may want to do is sell a marketing plan into American Express and say, get a card to your kid when he goes to school. That is, again, what I call contiguous advertising. It’s closer. It sits more comfortably next to the content that he has to offer.

Someone else was talking about the *USA Today* site, if it was sponsored by Acme Grocery Stores, or whatever. Again, to me, that’s too general a thing. My sense is that in the past 5 or 10 years, advertisers are expecting more transactional advertising; they’re expecting a cause and effect. It’s not just enough to go out there and make impressions. There should be some actionable item. There should be something you do once and you have that person’s attention. Don’t let them go away. Do something with them. Ask them if it’s okay to send them e-mail for some value-add, for some upgrade. Start a relationship. As Don Pepper says in the book *One to One Future*, this is a one-to-one medium. You’re marketing one at a time. Advertising historically, for the past 50 to 100 years, has been a proposition of one to many, but no longer do we sit and watch Ed Sullivan all together — well, he’s dead, so we’re not going to watch him — but, when we did that back in the ‘50s and the ‘60s, it was a shared experience. We all saw the Beatles and we all saw Elvis and so forth and so on. That’s not happening today.

I had a disagreement with somebody a couple of years ago. He said the Web will not be the norm; it will never be the norm. And I said I think that’s just it. There’s not going to be one norm anymore. There’ll be 100,000 norms. People will just siphon off into little slivers of

markets, little slivers of communities. You may be more in touch with somebody — the editor of WDFM, the *Web Digest for Marketers* that I publish, I don't know what she looks like; I've never met her and I talk to her every day. She lives in Marin County. This is a community, if you will — the word is so overused — a virtual community. I know more about the editor of WDFM, who's 3,000 miles away, than I do about my neighbor in the next apartment over, who's a couple of yards away. I think it's more about how to market to a community of interests.

There's a company called [lville], which I just visited the other day in New York. I think they have the right idea; we'll see. The site's not up yet, but they're looking at all things parental: raising kids, single parents, so forth and so on. Is it good enough for Levi's to advertise on that site? Just to put up Levi's as a hyperlink I don't think is enough. It's, "We interrupt this content for an off-topic Home Page brought to you by your sponsor." That's not where it's at.

Just look at yourself. There is a research term called "pulse universe." You take your own pulse and you go, "Well, I wouldn't do that; I'm not about to interrupt myself to click on — I'm in the middle of reading an article. Just because it's there, am I going to click on it? I don't think so. It's not my personal nature to do that. And if it's not mine, maybe it's not other people's, either." Probably that's the case. We're alike; we're unlike, but there's certain things that you can just intuitively know without a lot of research.

This is an exciting time; this is a very young medium. It's not going to take over print. It's going to be augmentative. Things that we look at today are going to — things that I do and say today are going to look as crude and naive in two years or less. Those Old Gold boxes that I spoke of earlier, they were made 40, 50 years ago and they look pretty funky to us now. It's not going to take 40 or 50 years for what's going on now. What I'm showing here today is going to take three or four years. And, to be honest with you, a year ago, stuff I was doing a year ago, and everybody else, looks archaic already. When you see things like *HotJava* and other things that you've seen here at the show, you can see where it's going. The orders of magnitude of sophistication, it's growing out much faster than, say, television rolled out, because people had to buy televisions. Television stations had to be erected. Here, PCs cost a \$1,000. Modems cost \$100 and less. Now they cost \$90.00. The prices just keep falling. It's Gordon Moore's law that every 18 months, power doubles and cost falls in half.

And George Gilder would say that that is true also now for bandwidth. That the cost of bandwidth we'll keep halving every 18 months, if not faster. I don't know if that's true or not. It's an interesting premise, though. If it is true, that means we're going to get a lot of data over the desktop, a lot of video and a lot of other things. Not just inbound, but outbound and upstream. I mean, to be a publisher — there's a little cartoon I'll use tomorrow at the general seminar on marketing. It shows a little girl at a lemonade stand and the headline is, "How much does it cost to put a Home Page up on the Internet?" And then she has a little sign underneath that says, "Lemonade, 15 cents, Home Pages, 10 cents."

The real question is how much does it cost to put a marketing plan up on the Internet? If you have an AOL or Prodigy account, you can put up a Home Page before the end of this lecture. That's not the question anymore. It never really was the question. It was a unique oddity. The early people, the people who came on, made their mistakes, as I said earlier — they made their mistakes early on in the game, so now, I'm looking and other people are looking at people who are going, "Oh, yeah, I made that mistake a year ago and it'll be interesting to see how long it takes me to get it." And there are just little things that you can tune in to now. I tend not to project out five years or ten years. There's enough going on right now that could be done better, like bringing the advertising banners further up on the page, making them a little bit more complimentary to the content that they're sponsoring. There's no more technology that has to happen now. Now it's just wetware.

[Tape change]

Larry Chase: ...content in an appropriate manner. To me, that's where the creativity is. I grew up as a copywriter in mainstream Madison Avenue ad agencies. For years, I won awards doing TV and headlines and all this great stuff. But, that medium has been done to death. I don't think there's a new idea left in it, and a lot of the old masters will tell you they think it's — good ads are basically reincarnations of other good ads from the '60s or '40s or '70s or '80s or whatever. When you think about it, just about everything has pretty much been done in terms of creativity.

I think that the exciting part of publishing creativity, marketing creativity is in the use of the technology and twisting it and turning it. When I got into the On-line Ad Agency, when I launched it a couple of years ago, I never dreamt that I'd been in publishing. I didn't think that I would have something called *Web Digest for Marketers*. That wasn't in my business plan. But then it suddenly dawned on me: When I launched the On-line Ad Agency and people came to look at it, I went, wow, hey, this is great, a lot of acknowledgment. And then it's like, okay, now the hits fell off. Now what do I do? How else am I going to get them to come to the Agency? Content. Yeah, that's it, content. I'll put stuff up that they want to know about. And that became *WDFM*. And I thought, I'll charge them for it. I was greedy. I said, I'll charge them for it. And then I thought, no, wait a minute, someone else a year from now is going to put this up for free, so it's better just to be early and not charge them for it and build that market share.

So, a relatively small player, like myself, suddenly has a publication that, within marketing circles, is pretty well-known. And the costs were negligible. I had no bricks, no mortar, no printing press, no cost of distribution. That worked so well we went backwards into print.

Somebody else asked me here, do the print publications mind that it gets published earlier on the Web, and that's an excellent question. In the beginning, they did. They said, would you please embargo — that is the news term they used — would you please embargo that information until we publish? I said, I don't think so. I said, that's one reason why you're on the Web — immediacy. For the same reason you can take that DEC laptop out of a catalog and just stop prompting people for calling on an 800-number to tell them that you don't have the product anymore. It's the same thing with content. It's like all-news radio for various categories. You've got all-news radio for die-casting or all-news radio for electrical engineers, only it's on the Web. Although, with audio now, it can be all-news radio.

But the point is that one of the reasons you want to publish to the Web is immediacy in a trade industry. So you really do have that up-to-the-minute kind of reportage for a very highly-defined market niche. And the other reason you want to put to the Web, also, of course, is for searchable databases, as I mentioned earlier. You can go back into Lexis and Nexis and do these very deep searches, which would take you way too long, particularly if you're a lawyer on billable time going through tomes of volumes of information by hand. Forget it. So, those are two very cogent reasons to publish to the Web.

And the gentleman who asked me the question was right on target. Print people are very, very leery of having things published ahead of their time — ahead of their press time. But as I pointed out to him, for example, *WDFM* gets printed in *DM News*. A hundred thousand people read *DM News*. In fact, more people read *DM News* off-line than on-line, so once I explained that to him, it was like, yeah, okay, that's all right. Because don't forget, not everybody is on-line. A lot of people share in this experience vicariously by reading about it or maybe they're going to be on-line in six months and they want to start getting an idea of what it's going to — and then they want places to go. I've seen people actually do this; they cut out URLs. Maybe we should make it like coupons, like dotted lines around it or something like that. But, people like taking URLs off of print. I've done ads where the headline is just the URL.

Actually, the Goodyear blimp should do that. They should put a URL on the blimp above the football games. That would be kind of fun.

Just as an aside, a very interesting aside: Goodyear publishes a lot of information about tires. A fairly low-interest category, as far as things go. I don't always go into the tire section every time I go on the Net. What's new in tires today? Hey, did you hear about those new steel-belted radials? Oh, I've got to go over there. No, it's pretty low-interest — unless, of course, I'm thinking about tires because I'm thinking about a new car. Maybe Goodyear should advertise over on Dealer Net. That's a possibility.

But, right now, Goodyear has this little blimp. It goes over this game called Two-Minute Warning. It's a football game, and on the blimp — you click the blimp and there's a challenge, the Goodyear Challenge. If you win — this is something that I worked with them on with their developers — if you win — you answer these questions about tires. I don't know anything about tires. Ah, but if you go to the site and you read — we're not going to really take too much of your time with this, but you just read a couple of our Home Pages and answer this, you'll get to go for a ride in the blimp over the Super Bowl.

Now they've had some interactive touchy-feely with you or what some people call hi-tech/hi-touch. You've interacted with this company, you learned something about tires and got thrown into the sweepstakes pool and you might wind up going for a ride on the blimp because you were playing Two-Minute Warning, which is a trivia game about football. That's not a bad tie-in. So, here's Goodyear publishing information about tires. Not the biggest draw in the world, but there it is.

Now, let's take another purchase. Let's take a grudge purchase, like insurance. Northwestern Life Insurance has this — oh, no, no, no. Let's talk about ITT Hartford. They've got an estate planner. They happen to focus on estate planning and insurance for such and life insurance. If you're interested in life insurance, maybe you're thinking about your own demise and you want to see what percentage should be in bonds and what should be in cash and how old are you and how many kids and college, and so forth and so on. You put all this information in and it spits back some information. You can't retire until you're 97. Well, you need to know these things.

So, again, this is publishing. It's not static, it's not print, it's not words, but it is a form of publishing.

I talk a lot about advertising agencies and why they're not getting this. And I think I need to repurpose that a little bit and talk about publishers, too, and say this: The Pennsylvania Railroad thought it was in the train business. It didn't realize that it was in the transportation business, so it knew not to compete against General Motors or against Delta, which flew me here. The same thing is true for ad agencies and, to some degree, for publishers.

Ad agencies think that they're in the business of advertising. They're not. They're in the information business, they're in the messaging business. Publishing is the same thing. You're in the messaging business. You have it over the advertisers, because you have better messages, you've got the content. The advertisers used to have the content. Back in the 1950s, Proctor & Gamble and Lever, they used to have these soap operas, because people who watched soap operas — the old traditional kind of advertising — people who watch soap operas buy soap, hence the name soap opera. But, Proctor said, "You know what? We're good at making Tide and Oxydol, or whatever, or Lava, or whatever. We're not terribly good at managing content, so ad agency, you manage the soap operas for us." The agencies, at one point, were in the content business, and they got out of it. They used to produce those pieces of content; albeit soap operas, still, it's content, for the clients. They're not doing that anymore. They farmed all that out and with that, they farmed out their value.

So that, to a large degree, both publishers and advertisers alike will go to ad agencies and say, what value do you bring to this? If you're farming out the [inaudible] and you're farming out the technology and you're farming out this and you're farming out that, what are you bringing to the process? Publishers are in a much better position. I just think they have to come up the ramp a little bit and get a little bit more creative and little bit more of a topical view, a higher topology and realize that it is messaging or the information business and it's not just a direct — you know, we bring *Time* magazine to the Internet verbatim. You need to do a little bit more with it. You need to use the technology.

Again, the first television commercial that came out looked like illustrated radio, because that's what writers and art directors — there were no art directors in radio, were there? — that's what writers knew what to write, was radio, so they just wrote radio with visuals. The same thing is happening here again. History is repeating itself here. A lot of the stuff that — most of the stuff that we're seeing on the Net is just repurposed, rehashed stuff that has been in brochures and in previous media. There's absolutely no value-add to it.

If you go to *Spiegel Catalog* right now — I can't think of a reason why I'd go to the *Spiegel Catalog* as opposed to reading it in print. The print one, I can take it with me, I can rip out a page, I can give it to him, I can put it on a bookshelf. If I go to the version of the *Spiegel Catalog* that's on-line right now, there's not any value-add to it. Why would I order from that on-line *Spiegel Catalog*? It's not terribly easy and I'm pretty uneasy about traveling my money over the Net.

You've got to give me an incentive. It may be a financial incentive, and it probably is, because it's cheaper to sell you over the Net than it is to sell you in a store. One of my clients is 800-FLOWERS. It's a lot cheaper.

Here's the acid test question: Why should I order over the Net? Why should I order a book over the Net if I can call an 800-number? That's something I'm pretty used to. I know how to use a telephone. I don't crash. I don't get "404 Not Found" on the 800-numbers. I get other things. But, how are you going to break my habit?

And I think the answer is I'm not going to break your habit overnight. Hardest thing to do in marketing is to break somebody's habit. We're creatures of habit. It's very difficult to say, don't pick up that phone; go to your computer; boot it up; get on the Web; launch TCP/IP; come to this Web site and buy it from us there because it's cheaper for us to sell it to you there. That's not exactly an incentive for the customer to help you out. Unless, of course, you partner with that customer and you say, I'll tell you what, it's cheaper for me to sell it to you here; I'll share the savings with you. Now we've got a financial incentive, and that's why software works so well on the Web and that's why publishing; i.e., information, works so well on the Web; because it's deliverable on-line. It's very difficult to send a hammer through a floppy drive. It doesn't travel that well yet. For information, for software, for that kind of content, that is perfect for the Net.

And that's why, as I said at the beginning of the lecture, publishing is being affected earlier than other categories of commerce, because it is a deliverable, and the early adopter companies are coming on the Net and are making their mistakes earlier rather than later. If it is a foregone conclusion that you have to be there and eventually you're going to be conspicuous by your absence, well then, you might as well bite the bullet and get there sooner rather than later and start making your mistakes today.

How much time do we have left? Half an hour? Okay. Oh, I didn't finish with books. Let me finish up on books here.

So we went to Bantam-Doubleday — let's go to Sunsite. Not there? Take my word for it, Sunsite's a great site. Sunsite is at the University of North Carolina. A couple of things I want to say about Sunsite. As that e-zine junction, pointers to pointers we showed you earlier and

Newslink pointed you to news sources, Sunsite is also good. It's in your package there, so if we don't get it, you can go home and pull it up on your own screens. Sunsite is good for its virtual library and it keeps track of all the new book companies that have come up on the Net. All of the new book publishers, book retailers, anything books. The Gutenberg Project, anything that has anything to do with book publishing. It's about as close as you can get to a comprehensive overview of what is happening in book publishing.

And the other thing I want to point to, while I'm on the subject, is this very interesting use of the nonprofit sector working with the commercial sector. It's not named Sunsite by coincidence. Sun-Lenter gave them the hardware, the servers, to do this site. Sunsite is a good site for — aside from all of the free information — again, it's free — of what's going on in terms of books on the Net. It's an interesting collaboration of commercial and noncommercial interests here. The site probably wouldn't be here if it wasn't for the good auspices of Sun Microsystems. And yet, at the same time, they're served rather nicely because every time we go — notice, I called it Sunsite. That was the name that I remembered. Actually, it's not called that. It's in the URL, I think, but people then begin to recognize brands by — particularly on EDU servers, on educational servers, this is a very interesting way for academic institutions that are strapped for money — as more and more are, with federal cutbacks, and so forth — it's a very interesting way to collaborate with the private sector to put up information that you probably already have. Probably the people who put this up were 20 years old. Somebody did it maybe for a final project or a thesis or something in grad school. Who knows? But there's a lot of intellectual power that is resident in academia. Boston is a good place to talk about this — that can be unleashed with the right combination of commercial sponsorship.

Now, on this site, I don't think it's going to be appropriate for out-and-out commercial offers. It's more the equivalent of like PBS or "Masterpiece Theater" made possible in part by... This is the Web equivalent of that, and I think you'll probably wind up seeing more and more of that as times goes on and as different academic institutions get to that point.

Just as an aside: I've seen a lot of things that have commercial value out there. For example, for a client, Hotel Discount, we found the same week that he launched, Airline Discount went up on the Net — I'm sorry — Airlines on the Net. There's this student at UC Berkeley, and he just has every single airline that's on the Net. I don't know why, but it's there. And then it was featured in a magazine. He got a tremendous amount of hits and awareness right after we set up a trade link relationship.

Now, at UC Berkeley, it was okay for him to point that to Hotel Discount. That's a commercial site. For some reason, at UC Berkeley, it's okay. There were other sites that we found, other educational sites that we found. We said, these people have great content. Let's point to them and let's see if they can point back to us and, you know, sometimes we were rebuffed and said, we do not accept commercial links on this site. It's an educational site. So, it's across the board. So, it depends on the trustees; it depends on who's running the Web server. This is one of those gray areas right now that's being hashed out and I think it's just on a case-by-case basis.

But, some people actually, you know — when we go out and we do these, what we call, "first contact" — it's a Star Trek term — who else is out there who's like us that we should be talking to for our client?

And about 30% of them might be educational institutions, out of which maybe about 30% of them feel comfortable enough to set up commercial linking relationships with a commercial entity that can go back and forth. Typically, they have not accepted money. I don't think we've offered any. I think we just offer links back and forth. Although it will come up at some point: How much per link if we buy a chair at your university or something. This is going

to be a very interesting thing to watch over the next year, I think, because one of the biggest knowledge bases on the Net, of course, are the educational sites.

And some of the most interesting technology that can be harnessed in publishing, incidentally — like Crayon, which is what we started with, is at Bucknell. I was talking to one of my clients just before coming up to Boston here, and he said, “I’d like that on my site.” Approach them, see what they think. So, as soon as I get back, I’ll call them up. I’ll go, can we mirror it? What can we do here? How can we work together? It might be that they’ll have nothing to do with us. On the other hand, the student might just say, give me a job. So, we’re not exactly sure.

With the few minutes that we have left, why don’t we open up for questions, if there are any. I suspect there are after what — two and a half hours or so? Any questions — I can’t see well, because we’ve got these lights on me, so if you can just shout out what the question is, that’ll suffice.

M: [inaudible]

Larry Chase: The question is: What would happen if we put a link from our Home Page to Crayon? We did that and they thanked us. That’s perfectly legitimate. You can point to anyone.

This gets into legal and copyright [issues], and I’m no lawyer and I don’t even play one on TV, but if you publish on the Web, it doesn’t necessarily mean that people have the right to take your information. Chances are, they don’t. However, if you are out on the Web, people can point to you without your permission. It seems that that is a perfectly legitimate thing to do. There are times when we want to simply point to other reference tools on the Web and there are other times that we want to have them resident.

For example, Hotel Discount. We found out that a lot of people using Hotel Discount are Europeans. So, let’s publish a currency converter that’ll be updated daily, because Europeans, when they travel, they often have to change their currencies, so it’s updated daily. So, we could have simply pointed to that, and we do right now. While the thing is under construction, we point to the one that we’re going to mirror, but as a hook, we can’t just go out and say, come to the Hotel Discount site; there you’ll find the link where you can go to a calculator, a currency converter. We need certain things resident on the server so we can say, come to the Hotel Discount currency converter server that’s updated once a day — you can find out how many guilder there are in the franc or how many pounds to the yen, and so forth. No, I don’t think people can stop you from pointing.

Any other questions? Just shout it out.

W: I have a multi-part question.

Larry Chase: You have a multi-part question, a Hyperlink question.

W: A Hyperlink question. Everybody talks about content being so valuable and you should be able to use the technology better, but it’s very expensive to come up with original content. So, my question is: Do you use third-party content in your magazine or original content? And also, if you do use third-party content, have you seen examples of how that can be repackaged so it does make the best use of technology? I’m talking more about content than advertising.

Larry Chase: Interesting.

W: Let me add one more thing. That’s immediacy. How often —

Larry Chase: Wait. I'm going to lose the first half of the question unless I answer that. Ask it succinctly. I'm sorry. Do that again.

W: The question was third-party content versus original, what do you use? And because original content is so expensive, can you give some examples or elaborate a little bit how technology can be best used —

Larry Chase: Okay. Okay, good. New content typically is expensive. You have to pay somebody to put it together and somebody credible. That's why we buy magazines, so that we trust the credibility of the editing source. It's a resource that way.

In terms of our content, to be perfectly honest with you, we repurposed a lot of our content. For *WDFM*, it was an internal document. It started out as, basically, a competitive reconnaissance report. Who is up on the Net? What is going on with marketing on the Net? We wanted to know that and, in fact, again, being perfectly honest, we thought that if we publish this stuff, our competitors are going to come in and pick it off of us for free. And it's true and they do. We see them in the Web locks. There's not much we can do about that. That's just cost of business. But we repurposed much of what we already had and what we were already doing, in terms of going out surfing, collecting the information and synthesizing it for our clients and doing competitive reconnaissance missions.

So we already had some of it and we added and we backfilled it and then presented it as a package, and that's exactly where the syndication model comes in. Because we do know how expensive it is to create good, original content, content that draws, content that's attractive. That's why it's an attractive model to syndicate, because I can turn around to another Web site and say, I'll sell you this information at half the cost of what it would cost you to produce it. Or I can turn to a print publisher and say, I'll trade you ad space in your publication in exchange for this content. It's almost a say-yes proposition. This way, he gets to cover the WorldWide Web; he doesn't have to train somebody up the learning curve to know what they're writing about; he's got somebody well-versed — and she's extremely well-versed, the woman who writes *WDFM*, Roberta Kane. So, it's a win-win situation and that's why we think — the expense of that content is why we think syndication is going to be something that you're going to see more of.

Now, what was the other part of that question?

W: Well, about immediacy. From what you've seen on the Web, how often is immediate? Is it daily? Is it weekly? Is it [inaudible]?

Larry Chase: That's a good question. It could be every 30 seconds. You know, if you go to the Netscape fish cam, it takes a picture every 30 seconds or so. On the other hand — well, *WDFM*, we updated it bi-weekly and then the editor insisted, let's have a daily update, because there was so much going on in the time that it took us to produce even the Web version of *WDFM*, that she said — her name is Roberta Kane. I call her Hurricane. She's just a whirlwind of force and she says, I can't just sit on all of this news for two weeks waiting for you to publish. I'm going to put up a daily site and she just went and put up a daily site. So, in that particular case, daily.

I would say no matter who you are, whatever market you're serving, these days, I think it has to be at least once a month, if not twice a month. And if you're in hardcore news, hourly or up-to-the-minute, or 15-minute lag. Like, if you go to Stock Tickers, there's a lot of them on the Net now. There's just a constant run. You can put in stocks from the NASDAQ, American or New York Stock Exchange and get — you know, it's just a 15-minute delay, because real time costs them like \$20,000.00 a month or something like that, whereas 15-minute delay is

good enough for most people, unless they're actual traders. That's ongoing. That's, for all practical purposes, real-time publishing. Does that answer it?

W: Yes.

Larry Chase: Okay. Any other questions?

M: [inaudible]

Larry Chase: I like real-time audio. Has everybody here heard real-time audio? Most people. Real-time audio I liken to 1960s AM car radio — a little off frequency, but discernible, and that's fine. It's imperfect, but it's good enough to listen to a strip of music. There's a site now, I understand, on GNN, on the Global Network Navigator, that they just put up last week with Sony's sponsorship, that plays music strips, so you almost have an on-line jukebox — which is a form of publishing, after all — of music tastes. Is it perfect stereo? No. But if you want perfect stereo, buy the CD. But at least this way, you get a taste of it. You don't even have to go to the record store. You can just taste it there and if you like it, you can go to CD Now and order it on-line or go into the shopping mall and pick it up at your — do they still call them record stores, by the way? Music stores. Did that answer the question?

M: [inaudible]

Larry Chase: Oh, gizmos. Currency Calculator is a good gizmo. That relates to my travel client. I've seen banks use mortgage calculators — That's a neat gizmo. I saw Mr. Potato Head on the Net Friday. That's an interesting gizmo. I haven't figured out how to use that yet.

Again, going back to the creativity. In my mind, the creativity in publishing on the Net is taking a look at those gizmos, looking at Mr. Potato Head, and then figuring out how to make that apply. To me, that's where the creative energy lies, is in taking the technology and turning it into marketing.

TUTORIAL WINDOWS SOCKETS SPECIFICATION

SPEAKER
Michael Baldwin
President, Dart Communications

Michael Baldwin: Hello, and welcome to our Window Sockets Specification Tutorial here at Internet World. Its subtitle is, "How to Develop Infinite Aware Windows Applications" and we'll be talking over a broad spectrum and hopefully we'll catch everyone's interest, your specific interest. But during the tutorial, if you have a question, I welcome all questions from the audience to address particular issues that are of interest to you as we go along.

Down at the bottom here, is my E-mail address, along with our Web page at www.dart.com.

A little bit about myself: I developed my first Windows 2.0 TCP/IP application in 1990, using [inaudible] product, which was an Internet networking card. We commercialized the first WINSOCK TCP/IP protocol library in February of '93 and that was called TCP++ and that was even before the Windows socket specification was established and we participated in setting that specification and testing against it with our product.

My company develops and licenses the Power TCP protocol libraries for Windows and those were introduced in 1994, covering TELNET and TCP protocols. Today our company licenses libraries that support these protocols here that are available as C++ libraries that I spoke about yesterday. After this presentation, if any of you are interested in the subject matter, I can go over that a little bit as well as the DLL's, VBX's, OCX's that are front-ends that we put on those class libraries to fit them into a multiple of different development environments. So, I am very familiar with WINSOCK.

Our session goals this afternoon are first to provide an understanding of TCP and UDP communication basics and once we have an understanding of that, we can move forward to cover two upper-layer protocols, which are TELNET and FTP, that we've selected. We'll talk about the WINSOCK specification; why its important and how you can use it for TCP and UDP access and we'll probably talk about some of the limitations of it also. Then we'll talk about how you can access WINSOCK from various development environments, including Microsoft compilers, Visual Basic, Power Builder, Adelphi and other C compilers.

Before I go any further, do we have any experienced WINSOCK developers in the audience? Nobody to challenge me? Oh, don't make it too easy. . . . How many people here are managers that just want to learn about WINSOCK for purchasing decisions? Okay, how many people are developers? Okay, that helps me. We'll have something for everybody here. So, we'll split the talk up into three sections and we'll break at a place about halfway in between for a quick ten minutes.

First, we'll talk about UDP and TCP basics, TELNET and FTP; what those protocols are. Section two, we'll talk about the WINSOCK interface specification, its history, why it's important and some of the details of the specification; and in Section three we'll talk about development environments, introduction to TCP/IP protocol libraries. It's not enough that you simply understand what the WINSOCK.DLL means and what that specification is, if I don't give you, perhaps, a couple clues as to how you can access that from different development environments that you will be working or your development staff will be working in.

User Datagram Protocol. . . Transmission Control Protocol. I always forget telling something about terminal network protocol and file transfer protocol.

First of all, UDP or “User Datagram Protocol” is connectionless. That means you can send a packet from Point “A” to Point “B” and from Point “A” to Point “C” and then to “D”, so these packets can be individually addressed to an address [at] a port number. They are block-oriented. That means that the packet stands alone on its own two feet. It’s not part of the stream, to compare it to TCP. So if you send 512 bytes the user will receive 512 bytes in the Datagram packet. There is no guaranteed delivery, which means that just because you send it doesn’t mean it was received.

Typically a UDP protocol builds an acknowledgment into what goes on. So the nice things about it are these packets are individually addressed, so from one single source port, meaning that you open up a single socket, you can address to any socket or any port, so you can use a single socket for more than one purpose if so desired. Another benefit is that broadcast packets can be received by all hosts on a local network segment. That means that by addressing a UDP packet to the 255.255.255.255 address, you can reach all hosts that are listening on that port on that network.

M: [inaudible]

Michael Baldwin: Yes, you do. So you specify the port and then all users listening on that port will receive that and likewise you receive. . .

M: [inaudible]

Michael Baldwin: . . . If you will compare it to TCP, which is a connection-oriented protocol, Point “A” to Point “B”, you could only send over that connection. With UDP, because you have a single source, you can send it there, you can send to there, you can send to there, so it can be used to reach multiple hosts. And of course you receive all packets that are addressed to the port you bind to, so that’s the other side of it, so if you bind to port 25 and send out a broadcast to port 25, you’ll get it too.

M: [inaudible]

Michael Baldwin: Could you restate the question?

M: [inaudible]

Michael Baldwin: Can another entity get into the port? Bind to the port? No, only one application can bind to a port.

The port concept is [TCP/UDP’s] way to multiplex. So you multiplex by many applications [bound] to different ports, so that network traffic coming into those ports are multiplexed to the proper application.

Yes, sir?

M: [inaudible]

Michael Baldwin: By “application” I mean it could be three FTPs or, yes, by any application... any task in your system.

M: [inaudible]

Michael Baldwin: Absolutely. Many companies will use custom protocols for their own purposes. For example, most of the TCP/IP networking vendors with the stacks will use a custom protocol to send licensing information across the network, typically the user would not know about it unless they're doing. . . they've got a "sniffer" on their network. That's a typical application for a custom protocol who's licensing.

Okay, a typical UDP session. . . in order to do this you need to create a socket, that's a function call; bind it to a port address, it's a function call; set options, that's a function call; and notification choice, which is another function call. Then once you do all that, you can send and receive data according to the protocol being implemented. By that I mean, if I was implementing TFTP, which is based upon UDP, there are some rules. There are some protocol rules that I adhere to in order to make my TFTP client interoperable with a TFTP server that may reside [at the] host.

M: [inaudible]

Michael Baldwin: Okay, good question. A "socket" is a term that refers to a communication porthole, if you will, or a socket. . . they call a "socket", you can compare it to a file descriptor, under UNIX, where everything is a file descriptor. . . that was model they went after. Okay, so. . .

M: [inaudible]

Michael Baldwin: Yeah, the. . . it's the same concept, but it isn't . . . but under UNIX, they tried to make it look like a file, even though it wasn't and they called it a "file descriptor", even though it. . . wasn't one. In that paradigm, it was brought forward into the WINSOCK specification, so it's a descriptor of a dynamically-allocated communications mechanism. It's usually a number that starts at 1 or something and just starts incrementing.

M: [inaudible]

Michael Baldwin: Yes, sir.

M: [inaudible]

Michael Baldwin: You could. . well, when you bind to the sockets, only binding to the socket on the local host or if you're a multi-homed host, you could bind to two on the same port.

M: [inaudible]

Michael Baldwin: Yes, that's a local. "Bind" refers to your local machine, so you're binding the socket descriptor to an address specification for receiving or sending, because when you send a UDP socket, there'll be a source address and port in that packet when it goes across the wire. Then you close the socket.

This is about all we're going to talk about with UDP today. They'll be a little bit more later, but. . . TCP is a little more complicated, and that's where 95% of the applications will use TCP, so we won't talk a lot about UDP anymore until we get to the WINSOCK section.

M: [inaudible]

Michael Baldwin: Yes, sir, exactly.

M: [inaudible]

Michael Baldwin: You have to enable the communications on the port, before any communications can happen. It's often used for dynamic discovery, so that if you are constructing a special application on your network and you didn't want all your users to have to configure what IP address was the server, you could just broadcast a packet and then the server couldn't respond to the packet and then tell you where to make your TCP connection, for example. That technique is used as often as. . .

M: [inaudible]

Michael Baldwin: The technique for dynamic discovery on network? You can have all of your applications listening up on a UDP port, reserved. That's just for you. Let's say that you choose Port #2000 and then if you want to communicate with a server on the network, all you do is you send a little request out to Port 2000 and broadcast it.

M: [inaudible]

Michael Baldwin: As the client. You don't know where the server is, so you broadcast the UDP packet and the server responds with, "It's me". And then the IP address is there and then you make a connection to them.

M: [inaudible]

Michael Baldwin: The limit is a short, unsigned, short, so it's typically 1 through 64k.

M: [inaudible]

Michael Baldwin: Nothing at all. No, the first one will work and the second one will fail. There's a concept of reserved port maintained by the Internet or the Nick, I think. The people that worry about this type of thing, like there are reserved port numbers like 20 and 21 for FTP, TELNET for 23 and if you have an application that wants to use one, you can register your application port with the Internet authorities.

M: [inaudible]

Michael Baldwin: Yes, at the last page of my presentation, I've got a couple references. You can look in there. And there's a Web [inaudible] course there, too. The "InterNIC", it's called.

M: InterNIC?

Michael Baldwin: I'm not sure of. . . perhaps someone knows the address of that.

[inaudible response]

Michael Baldwin: Pardon. InterNIC? Internic.nic.com — could you repeat that one more time for this gentleman; he's trying to write that down.

[inaudible response]

Michael Baldwin: Yes, sir.

M: [inaudible]

Michael Baldwin: Then you make a connection back to 78? on TCP? Okay, so what he did was he broadcast his UDP request over Port 2000 and then the server said. . . responded to him and said, "Connect to me on Port 78 (or whatever)" and then he made an active TCP connection to Port 78.

M: [inaudible]

Michael Baldwin: The Transmission Control Protocol is connection-oriented as we discussed. Point "A" to Point "B" and you can't talk to anybody else over the same port, so that's how its different.

It's a stream, meaning that when I send out 10 bytes and another 10 bytes, send out another 10 bytes, we have no idea if on the receiving side, he'll get 1 byte, 1 byte or he'll get 30 bytes in a chunk. That's called a "stream" and there's no record blocking. Very important to understand that. Transmission Control Protocol is Berkeley by nature, in that when a user at a terminal emulator types a key, one ASCII character is surrounded by about 40 characters of packet information and is sent and nondeterministic when the person's going to type. And likewise with the FTP file transfer. You know, you're doing nothing then all of a sudden you're downloading a file as quickly as possible, so this is bursty communications as opposed to the telephone, which is 64k a second.

It's reliable end-to-end communications, meaning that you don't have to check for errors, because the underlying protocol checks for errors for you.

M: [inaudible]

Michael Baldwin: Yes. So when you have a TCP connection, you can assume that data is reaching the other side unless informed otherwise. But you can assume how quickly it gets there.

M: [inaudible]

Michael Baldwin: Connections? They are of two flavors: You can make an active connection, which is the typical terminal emulator that connects to a remote host and logs in or you can be a passive connection, which means the server, as it does with the TELNET demon, accepts the connection on Port 23 and has a handler process that handles the connections for the operating system.

Okay, and you can do this same thing. You can build a server on a PC platform under Windows 95 or Windows NT, just as easily. And we'll talk about that.

M: [inaudible]

Michael Baldwin: You use. . . well, you look at your application and then determine which features fit you best.

M: [inaudible]

Michael Baldwin: Yes, the best example was the gentleman in the back doing dynamic discovery. That's the only. . . UDP is the only way you can do dynamic discovery to broadcast a request across a network. Okay, and the best example of using TCP is a TELNET connection, where you want the data stream to be reliably sent and received. And you want [to] stream communications.

M: [inaudible]

Michael Baldwin: TCP and UDP are both built on IP.

M: [inaudible]

Michael Baldwin: Yes, sir. UDP is very close to IP; it adds addressing information on the packet along with a couple other things like a port number, because it knows what a port number is and IP does not know what a port number is and TCP adds that information and also does error checking and acknowledgments.

Yes, sir.

M: [inaudible]

Michael Baldwin: A connection under TCP is uniquely identified by your host address, your port number, the remote host address and the remote port number. That "fourtuple" right there uniquely identifies any TCP connection on the Internet.

Lively group! Lot's of questions! I didn't get so many questions yesterday.

Okay, typical active connect: We're going to describe this in broader terms before we talk about the function calls and snow everybody.

You want to create a socket, number one, you bind it to a port address, just like UDP, you set options and notification choices, just like UDP and then you launch a connection request. So that's the last step there; it's unique. And you catch notification of the success or failure of the connection and then you send and receive data according to the upper layer protocol, just like before; with a difference being that there is no record-blocking, so things can show up in a stream then it's nondeterministic.

Yes, sir.

M: [inaudible]

Michael Baldwin: I may have misspoken. I meant to say "dual-homed host", is where a host with two [inaudible] cards, for example, can have a unique IP address, so when you accept a connection, you can specify which host you want to reserve. . . establish that socket for.

Yes, sir.

M: [inaudible]

Michael Baldwin: "Notification" can be one of several mechanisms and I will talk about that on a slide coming up.

M: [inaudible]

Michael Baldwin: Absolutely. You can have 10 or 20. That's how we do it with like the TELNET Demon into a UNIX host. You can have a hundred people logged in, all to the same port. No problem. Because remember, the connection's defined as that fourtuple and as long as the source. . . and the source can't be the same. So the host address that you're connecting to, the host port that you're connecting to, as long as. . . one of the first two, which is the address it's coming from or the port it's coming from is different, there can be no duplication.

M: [inaudible]

Michael Baldwin: Absolutely. One to one.

M: [inaudible]

Michael Baldwin: Say it again, sir.

M: [inaudible]

Michael Baldwin: The question is: Can the same person open up two TELNET sessions? You certainly can. The reason is that your local port number will be different, because for two TELNET sessions you can't have the same local port number, as we talked about, so your fourtuple is unique. All right.

M: [inaudible]

Michael Baldwin: Yes, we will. We'll have different local port numbers, even though the port numbers that the host is using are the same.

M: [inaudible]

Michael Baldwin: They are IP packets. Yes, so there are IP packets that are going over the network that negotiate the connection that you are not aware of at the TCP layer.

M: [inaudible]

Michael Baldwin: Yes, sir. You'll be notified. . . we'll talk about that mechanism [a bit later]. . . Then you close the connection when you're done. When you close a connection, the other side of the connection is notified that you've closed the connection,

Okay, typical passive connect. This is a harder. . . the harder of the two with a little bit more going on. We create a socket, bind it to a port address. . . sound familiar. . . set options, notification choices and then launch a listen request. And "listen request" just enables the socket to accept a connection. And that happens very quickly. Now, a connection request comes in and then your application is notified of the connection arriving and then it's up to your application to accept the new connection.

So, there's actually an accept call that says, "Okay, we'll accept the new connection" and that's important, because we have to manage that new connection, we have to accept it. Then we have to set up dynamic structures to support that, because what if we accept 10 connections, so those are 10 management things that we have to have and then we close the

connection when we don't want to accept anymore connections. And, of course, we have to close those connections that we accepted.

M: [inaudible]

Michael Baldwin: Yes, sir. Oh, you want to go back? Okay.

M: [inaudible]

Michael Baldwin: I'm sorry. Pardon? As I mentioned early on, I've got all the PowerPoint demonstrations, I mean "files", that I can give to you today, including my presentation from yesterday; if you have a diskette.

M: [inaudible]

Michael Baldwin: Yes, I think that's a good idea, if you look at my Web site in a couple of days and do an FTP transfer. I'll put it out there. That's a great idea.

M: [inaudible]

Michael Baldwin: There you go.

M: [inaudible]

Michael Baldwin: No, sir. What I'll put up is a PPT file. I'll put the PPT files up that can be downloaded and then you just view it.

M: [inaudible]

Michael Baldwin: Oh, I've got handouts up here, so come up and get a handout.

M: [inaudible]

Michael Baldwin: Okay. TELNET. Let's talk about what "TELNET" is, so that we can figure out why we're here, because their upper-layer protocols are the reason that we write to WINSOCK to begin with; to solve problems.

So, TELNET is used to log into [a] remote UNIX host, commands are embedded in the data stream and the data stream has to be parsed, because you have to search for the commands, which must be responded to.

I'm assuming that there are some people in the audience here that are interested in WINSOCK because they want to write an application and, by far, more TELNET applications are written than any other type, as far as when we license our software, I've got more sales for our TELNET libraries than any other. So I thought it would be instructive to show this.

M: [inaudible]

Michael Baldwin: Good question. A typical application is a customer of mine that has multiple UNIX hosts in his organization and he wants to write a custom application that goes out to

those UNIX hosts and performs a task, perhaps on some kind of recurring basis, to capture information.

So an example would be to use TELNET in the background of your applications. So, behind your GUI, it doesn't have to be even shown. . . [it] can log into the remote host as specified in your organization, perhaps run a Sequel engine, do a query, get that current information and then build a graph.

M: [inaudible]

Michael Baldwin: Absolutely, you can build a server on a Window NT box, for example. . . [and] return any kind of information that you may be interested in.

M: [inaudible]

Michael Baldwin: You can. . . there are companies that offer Windows NT servers and we are developing one. . .

M: [inaudible]

Michael Baldwin: Oh, I'm sorry. Yes, Windows NT Work Station or Server can both be used to build an application of any of the types that we are discussing.

M: [inaudible]

Michael Baldwin: Only if you buy a TELNET Demon from somebody. Okay.

M: [inaudible]

Michael Baldwin: Well, it's probably easier to buy one for a hundred dollars than it is to write one.

M: [inaudible]

Michael Baldwin: Yes, sir, I have one under development and I think there are other sources.

M: [inaudible]

Michael Baldwin: Yeah, we're demystifying a lot of things here. And that's really good, because it's in stark contrast to the rest of the show. Okay, what the parser [does is] separate the data into commands and data. So if you build a TELNET application, that's what you have to do with the data that you receive over the socket.

Okay? Then you have to respond to those commands otherwise, as I note here, most hosts will halt communications if you fail to respond.

M: [inaudible]

Michael Baldwin: [What is] "the command" called is the question? They're called "TELNET Option Negotiation Commands" and they can occur at any time. I'll refer you to the RFC that describes what those commands are. Okay.

The typical TELNET connection is much like TCP, but typically you will connect to Port 23, then you search for those control sequences and then respond to them with, "I will do" or "I don't want to do those sequences. . those options". One will usually display data to the user for viewing and when you buy a terminal emulator from someone, that's what you see; however, you can use the same mechanism in the background as I spoke of before, to collect information across your network or the Internet for that matter, bring it back and if we have time we'll even demonstrate a connection to my host in Syracuse.

Usually you'll send ASCII data as the user types [it] in, but you could simply program it into your program and execute that, put a carriage return/line feed [inaudible] and run a Sequel engine on the host. Do any query you care to perform and capture the data coming back. You've done this.

M: [inaudible]

Michael Baldwin: The File Transfer Protocol deserves a couple of seconds, because that's the number 2 best seller in my product line, because people want it. . . it's the lowest common denominator as. . . in my benefit bullet, right there. Most common denominator for moving a file from Point "A" to Point "B". It provides authentication support in the form of the user name and password that you have to provide to log in or if you're an anonymous FTP, it's simply "anonymous" in your E-mail address.

Most file manager features are implemented and that's why when you go over to Delrina's booth and they'll show you their FTP, they provide you with a directory listing and all the files that are in there in the nice Windows environment, because it provides all that information and it supports binary ASCII transfers. A little known fact that is actually. . . means something when you're doing this, for a binary transfer, is an exact image; however, UNIX likes to standardize on an end-of-line sequence, because on UNIX, an ASCII file is just a carriage return at the end, but when you transfer a file off the UNIX host in ASCII mode, it will put a carriage return and line feed on the end, because that's the definition of the protocol.

So that's why when you get a file that was in ASCII mode, typically it's larger than you get it on your PC, because PC's like carriage returns and line feeds, like an edit box. The benefits are that its ubiquitous in that it's in every UNIX host, at no charge, even FTP; even Windows NT; Sparc Station and Server and its the lowest common denominator in any case, just for moving a file from Point "A" to Point "B". Its largest drawback is that it's inefficient for numerous files, because a unique connection is required for every single data file in order to comply with the RFC and that set-up time takes time.

M: [inaudible]

Michael Baldwin: Well, you certainly know. . . it cannot. It's specified in the RFC, but many UNIX hosts that you will come up against will not support that feature.

Yes, sir.

M: [inaudible]

Michael Baldwin: You send them serially, one after the other, over separate data connections. Yes, sir.

M: [inaudible]

Michael Baldwin: Yes, it would, because even though the RFC specifies some other techniques for concatenating files, and bring them across, not everyone standardized on it, so then nobody did it, because unless everyone does it, nobody can do it.

Yes, sir.

M: [inaudible]

Michael Baldwin: You know, the RFC doesn't say you can't do it, and when I design my libraries, I provide a mechanism for doing that and then when I started testing, I found out that it broke the server in order to specify a second one. So, the server forces serial transfers unless you wanted to have a separate FTP session. In fact I recently did this test for a customer: The question was, "Can you do a high-speed transfer on three files at the same time using our library?" And the answer is, "Yes, you can test it." Three different applications, but each one would have to process a file serially within the application.

M: [inaudible]

Michael Baldwin: No, actually there's a tighter loop in the middle there. Authentication happens first. . . good introduction to the next slide. . . [inaudible] control connection, pass user, log in information, over the control connection, create a TCP listening demon to do the first file transfer, pass the address and port of the demon over the control connection, pass instructions for the file transfer control, accept the connection and transfer the file data, then go back to Step 3. Create [a] TCP listening demon, pass the address, pass the instruction, accept the connection, transfer file, etc.

M: [inaudible]

Michael Baldwin: Yes, sir.

M: [inaudible]

Michael Baldwin: Oh, okay.

M: [inaudible]

Michael Baldwin: Well, you'll have to talk to your UNIX systems administrator. I'm not a UNIX systems administrator, so I don't have that information. Okay?

Let's see, we've got time to start probably on the Windows Sockets specification and you came in late; we do have a handout up here.

[Tape change]

Michael Baldwin: I love to talk about history, since I'm an old timer in this field, having started really in 1990, with lots of experience now, but the early DOS TCP/IP vendor's FTP software, which you'll see out there on the floor and Exolan or the EXOS line, which was actually bought out by Novell and became the landmark replacement for DOS product line, those two DOS products were not WINSOCK, but they were like a socket library, like UNIX and FTP still provides that interface to the kernel.

Those are proprietary libraries and the things wrong with that is that the developer of the application statically linked those libraries and since he statically linked to the libraries, his application was married forever to that kernel implementation. So, if I, for example, wanted to build an X-Server that would run on [the] Hummingbird, I would have to pick stacks that I would support and I would have a version for FTP software and I would have a version for Exolan because I would statically link into their libraries, okay.

So that's why, as far as history goes, that Manage and Distinct and the other TCP/IP vendors out here, all have a huge laundry list of applications, because history-wise, they are the only people that could write them and have the distribution mechanism, so all those applications which were bundled with the Kernel were sold as a complete package. And that went on for years. Okay.

Now the first TCP/IP vendor with a DLL was NetManage and I talked to those people and that was a big risk. I mean they broke away from the stack library mold and they said, "Well, O.K., I'll provide this dynamic-link library to my protocol libraries" and then Vendor A, Vendor B and Vendor C, they could write to that DLL, but it was an interface, so it was an interface specification and it was really the prototype for the WINSOCK specification. So, it was a little bit better.

Yes, sir.

M: [inaudible]

Michael Baldwin: Why aren't there sockets on the Mac? I'm not familiar with the Macintosh development environment, but I do believe that there is one interface library that does do sockets. I don't have enough information.

So proprietary libraries are part of Net Manage, but that was a huge step forward anyway. Now, once developers saw that, they said, "Well, why don't we have a standard across all of the kernel vendors. And if we had a standard across all the kernel vendors, then my application can run on all those kernel vendors." So [that] they don't have a proprietary advantage and, basically, lock in their users to their solutions. So Window Sockets was born in 1992 and the specification process spanned about a year there and some leaders in that field were NetManage, which was a very active leader in others.

Now, when the WINSOCK specification was established, all of a sudden some vendors with low-market share supported it. It was a great idea for them because it would make their product more valuable, because then [you could] mail a package from your door, for example, [and it] could run over WINSOCK. So a company could buy a TCP stack from Company "X" and buy Eudora and maybe buy a VT-220 emulator and run in that. It really ticked me off at the time, but vendors with market share. . . did not want to move to WINSOCK, because if you already have market share, it's in your best interest not to open up to a standard like that. Okay. But even Novell, with their horsepower, found it to their advantage, within a year, to release a WINSOCK DLL interface to their stack. Okay.

M: [inaudible]

Michael Baldwin: I'm sorry, Novell LAN Workplace for DOS. They provided a WINSOCK DLL interface. Basically an interface layer that would talk WINSOCK on the top and talk to their proprietary or their kernel on the bottom, but it gave them that layer there. My company was vigorously testing against all these implementations with our libraries while this was going on.

Why is it important?

WINSOCK is important because, number one, apps will run on any TCP/IP transport supporting WINSOCK. There are a list of vendors and Microsoft thought it was such a great idea that they made it part of the operating system. Which is my point two: As Microsoft and Windows '95 are adopted, Windows '95 is especially adopted on every desktop, the potential market of any application written to WINSOCK expands.

Michael Baldwin: Yes, sir?

M: [inaudible]

Michael Baldwin: Trumpet? Yes, "Trumpet" is a WINSOCK implementation also.

M: [inaudible]

Michael Baldwin: Well, it's not exactly free. There is a licensing fee involved if you are a company and it would be free to individuals using it for personal use.

M: [inaudible]

Michael Baldwin: Trumpet? Not to my knowledge. I was involved with the working group and there was a long list, but Trumpet. . . he may have participated. . . his name is Peter. . . [inaudible]. . . no, it's not Trumpet. Peter. . . he's Australian, I believe, so for geographical reasons I don't think he participated with a presence, but he may have had E-mail input.

M: [inaudible]

Michael Baldwin: Oh, Version 2 of WINSOCK specification is not set yet. We'll support a mechanism for requesting other transports, like IPX, Novell Standard or other X.25, whatever, there's a mechanism for requesting a different protocol besides TCP.

M: [inaudible]

Michael Baldwin: Say it again, sir?

M: [inaudible]

Michael Baldwin: Yes, I.I only supports UDP and TCP.

M: [inaudible]

Michael Baldwin: Okay, that's a good question: What do PPP and SLIP have to do with WINSOCK? And the answer is that those two protocols are used at a lower layer for transport across serial lines. You can't even specify a particular lower-level transport under the WINSOCK interface. The WINSOCK interface only gives you access to UDP and TCP and does nothing for you as far as how that information gets to you. Okay? So it [has] absolutely no interface for specifying PPP; for specifying dial-up information or other information that is required to establish [any] Internet kind of activity.

M: [inaudible]

Michael Baldwin: Yes. It's surfaces at the WINSOCK the only service that you can request is TCP or UDP, even though PPP could be routing multiple protocols like IPX, intermixed with your IP packets.

M: [inaudible]

Michael Baldwin: No, you cannot. The best you could do is specify multiple Internet addresses for the different interfaces and then specify the Internet address, which you can do.

M: [inaudible]

Michael Baldwin: I'll talk about that in a slide or two. Gotcha. Okay?

ComSoftware 101: This slide is labeled "ComSoftware 101" because there are three types of interfaces into communications that can be used via software. And the three types are, starting at the top (and this is something I had to learn before I could get to square 1): "Synchronous Blocking" A Synchronous blocking function is a function that captures the thread or the thread of your program, execution, and returns from the function when it either is successful or it fails. It is very typical in UNIX operating systems, which is a multi-threaded operating system, especially before user interfaces like Motif were invented where you needed response on other parts of your program. It was typical, for example, to make a connect call that was synchronous blocking, that a second later, perhaps, it would return with a success or failure of the connection. That was typical in the UNIX environment. And it would not interfere with any other processes that were going on.

Now, synchronous non-blocking? Well, "nonblocking" refers to the fact that it goes into the function and returns without blocking for an indefinite period of time. So, you capture the thread, it returns quickly and that's a technique that is available through WINSOCK, as is the first technique. And it was very typical under DOS where you would typically poll for completion information.

The preferred event-driven approach that we utilize in our libraries and that I would recommend that anybody use that interfaces to WINSOCK, is asynchronous non-blocking. And what "asynchronous" means is that you'll be notified, in an asynchronous [manner] when it is finished. And it's non-blocking, because it doesn't stay in the function while this is all happening. It returns immediately, sets things in motion, then you're notified [of] any event triggered.

That's implementing the WINSOCK specification, by setting a couple notification choices in the IOC/TL socket function. You can specify a Windows message that will be generated to your Window to notify you of a connection, notify you of when there's data to receive on the socket and notify you when you can send more data.

So WINSOCK can call blocking functions if you want, but under Windows for Work groups, I haven't verified it or not under Windows NT, what the actual case is, but the specification says that you can only have one blocking function at a time in the WINSOCK library and I don't know if that really applies to Windows NT, but it's in the specification at any rate.

So that second blocking call into the WINSOCK library will fail and it doesn't have to be the call from your application; it could be a call from the second application that's trying to do something, so it's. . .

M: [inaudible]

Michael Baldwin: Is there any reason to not use a blocking function?

M: [inaudible]

Michael Baldwin: There is no reason except that it's a little bit harder to set up, because it's event-driven and you have to set up some things, so that's the only reason is that it takes a little bit longer to set up the event mechanism.

M: [inaudible]

Michael Baldwin: . . . computer. . . into the WINSOCK DLL is allowed.

You can call non-blocking functions on a timer, but polling is inefficient, so you can, for example, call connect [e word] block and keep checking. Call connect success. So that is an alternative mechanism, but as I stated earlier, we recommend using the trigger mechanism for all WINSOCK interface tasks.

You can't interfere with another task when you do it that way and all it means is that you handle things on event notification, which means you just put your code in someplace different.

A typical active connect [which] we talked about earlier is all those things: create a socket, bind, set options, notification choices and catch notification of a connect. We'll go through the actual calls at a conference desk, since this is a WINSOCK 1.1 specification.

The first thing we do is call the socket function. It's a socket function and one specifies the socket stream or socket [inaudible] for DDP socket and I'm not going to go into intricate detail here, saying what all the parameters are, but I'm just going to talk about the important ones. Just so you have a feel for it and you can look. The WINSOCK 1.1 specification is available on the Internet and my last slide will tell you where you can get it.

Then you bind it. Okay, so you take your socket ID, now you've got that and its one of the parameters of the bind and you set the port number and address, if desired. You cannot set a port number and an address if you do that. The library will assign one to you that's not used. So you don't have to specify one. In most cases you had no need to specify one.

M: [inaudible]

Michael Baldwin: There's a structure. . . a C structure that is a parameter of the bind statement where you fill in the blanks, port and address.

M: [inaudible]

Michael Baldwin: Yeah, I think only one is supported if you look. . . it's pretty detailed; I didn't want to put it in here, but there's a network family that you specify to. And I think only one is even valid.

M: [inaudible]

Michael Baldwin: Yeah, I'd have to refer you to RFC and [the] WINSOCK 1.1 spec, it describes that. It's about 200 pages.

The WSA [selects] its root from the select function in the UNIX socket library. What it does is it establishes what notification you desire and it takes as a parameter the Windows handle of the window you want notified, the message number, the user message number that

you would like it to use for notification purpose and then it reports any errors as parameters in wparam and lparam. It reports whether or not the socket, a listening socket for example, has just accepted the connection or is ready for you to accept the connection on it, or the connect just occurred, or there's data for you to receive, or the WINSOCK buffers can accept more data that you are sending. So that's the type of information that using this mechanism here can trigger. . . it's called [event]-triggered and there's several pages of description on this. . . on the specification that I'll refer you to for greater details and there's a lot of detail there.

[File] control socket is the function that is used to enable or disable non-blocking operations, so you have to use this [for]. . . blocking operations so that there is async select. . . can be used for the event notification.

It can also be used to determine the amount of data that can be read, so within our library, for example, since we don't know the application that is going to be used, we have a dynamic buffer and when there's a large amount of traffic coming to the PC, we'll use this to check how much data there is. If our buffer isn't big enough, we'll dynamically allocate a larger buffer, read in all the data and report it up to the application. It also checks for urgent data, which is not normally necessary.

On the connect function: It takes as a parameter such things as remote address and remote port. It sets it in motion, some IP negotiation that attempts the connection and acknowledges the connection.

A blocking socket, as we talked about before, can capture the thread for several seconds and then return. You can use select to determine the completion of the connect request on a non-blocking socket. That is like the UNIX socket library select function or, which we recommend and is a little bit easier to use from my point of view, you can use the async select function to trigger the event notification.

M: [inaudible]

Michael Baldwin: Well, it depends if you allocate a thread for the communications or not. You may, you know, you may not or the typical programmer would not, and it's unknown to me whether or not you [can] do a blocking operation on the Windows NT operating system. . . the WINSOCK specifications says you only are allowed one.

Now, whether or not Windows NT allows more than one, I don't know. When you develop an application for [the] WINSOCK spec, you should adhere to the spec, because you can't assume any different behavior.

So if you were to do a blocking operation on a connect, there is a possibility that a competing application, also trying to perform a blocking synchronous operation, would be shut out, which is not a very friendly thing to do. So that would be the reason why you would not want to do that. Although we're developing a VT-220 emulator with multiple Windows and we're actually establishing a thread for every [NDI] child.

M: [inaudible]

Michael Baldwin: It's really possible that it's okay, but you have to develop it to the lowest common denominator, because, I mean, one user may be using a kernel from a different manufacturer, under Windows NT for a particular feature and then you would not want to have your application break.

M: [inaudible]

Michael Baldwin: The “receive” function is used to receive data on TCP connection, so you specify like [inaudible] to your buffer and the length of your buffer and they’ll just fill your buffer with as much data it has or the length of your buffer, whichever is smaller. If its a blocking socket and no data is available, it will capture the thread within the function until at least 1 byte is there, which is not a very friendly thing if you have a nice interface all built up. A result of zero bytes in the case of [a] closed connection is the only positive indication of a closed connection [so that] when you do the read and you get zero back or do the receive and you get zero return.

M: [inaudible]

Michael Baldwin: That’s correct. There is both, actually. There is an event notification of a FD closed, however it’s kind of like informative only. It doesn’t indicate that you’ve read all the data of the receive buffers, so the only positive indication is a zero return from the receive function.

M: [inaudible]

Michael Baldwin: No, you cannot. You’ll get notified of when 1 byte is there and then. . .

M: [inaudible]

Michael Baldwin:. . . does what do any buffering?

M: [inaudible]

Michael Baldwin: Yes. The question was: If there’s 1 byte in the buffer you get and after you receive notification and by the time you service the request if there is more data in the buffer, [will] it take all of it if you attempt to? Is that correct? Is that what you were asking?

M: [inaudible]

Michael Baldwin: The typical application is that the processing speed is hugely fast compared to the communications, so that you want to be notified. . . you want to know about just a single byte, because that’s typical when a TELNET demon, for example, receives every single byte on a keystroke-by-keystroke basis.

The “send” function is used to send data over the TCP connection and the strange thing about it is that there’s no guarantee that it will accept all the data that you submit, so [if] you want to send a thousand bytes. . . it may accept 10 bytes, okay. So what is happened here is that it’s accepted part of your message, but not the whole thing. So when we built our libraries, we had to build an entire queuing system, where. . . so I have a queue of buffers, so that basically as the queue . . . the queue has to be emptied at the pace that the WINSOCK kernel can accept the data.

M: [inaudible]

Michael Baldwin: There is no function that allows you to find out how much data the kernel can accept.

M: [inaudible]

Michael Baldwin: No, I'm not sure if it's really necessary. It does impose a burden on the application developer, though. That he cannot assume that all the data can be accepted. That is true.

M: [inaudible]

Michael Baldwin: The way it operates, and this is the way our libraries implement TCP, is that, for example, 10,000 bytes are presented to the send function for transmission; 100 bytes are accepted. We make an internal buffer of the remaining and its in front of the queue and then we have FD send notification enabled so that we're notified when the WINSOCK layer can accept more data and we try to send all its remaining 9,900, if my subtraction is correct and then it will take another 200. . .

M: [inaudible]

Michael Baldwin: A very good question; it's called "back pressure." Because of the way the TCP protocol is implemented, meaning that there is an acknowledgment and there's this buffering that goes on, the actual mechanism is that the IP packet is sent and if the application on the receiver's side does not receive the data, it just sits there in the buffer, okay.

Then the next IP packet comes and there's room in the buffer, so now there's two IP packets and the acknowledgment is sent back, "Yes, this is what I've got and I got it" and then. . . but no receive. . . but the receiver is not taking the data out of the communications layer yet. So the third IP packet is sent; however, the receiver no longer has any buffering space, so it drops it. It's dead. It times out. If the time out period is typically like 20 seconds, there's no acknowledgment that says, "I received IP packet No. 3", so what happens is after 20 seconds, another one is sent and this continues to happen. If it continued to be dropped, there's a notification that there is a network failure. However, what is typical is that the receiver is like a slower host and it's just processing things more slowly, so that the second attempt is acknowledged. Okay, and that's called "back pressure" when this happens, when these time outs occur, it's called "back pressure" and it's the way the TCP compensates for the fact that different hosts. A Cray talking to a 286, okay, this probably happens a lot.

M: [inaudible]

Michael Baldwin: They could have. In fact the value-add for our library is that we do all the buffering in that we provide a notification back saying that all of the data has been submitted to WINSOCK, so that's a value-add of our library that compensates for that deficiency.

WINSOCK 2.0, there will be a mechanism for providing, like, an entire buffer. It'll make a local copy, just like what we did. I think that's being addressed.

M: [inaudible]

Michael Baldwin: A very good question. Microsoft distributes an MFC class called "C-socket" and there's a very thin wrapper around the socket library and does no more than put the send function in as a public method within the class and does not provide any increased functionality. Okay. That's, I guess that's the value-add for a library like ours.

Yes, sir.

M: [inaudible]

Michael Baldwin: Priorities for what?

M: [inaudible]

Michael Baldwin: No, there's no mechanism for doing that because we're a stream. First in; first out.

M: [inaudible]

Michael Baldwin: We'll quickly close with this slide, I think. "Closed socket", closes the connection after handshaking with a remote host so the remote host can notify the application that communications are closed, although a socket parameter can be used to specify our hard close, which means that no handshaking occurs, so it's a non-graceful close.

M: [inaudible]

Michael Baldwin: I'm sorry, sir?

M: [inaudible]

Michael Baldwin: Absolutely. Either side can close the socket.
Okay, we'll continue with this after a brief recess. Let's take about eight minutes.

[Break]

[The initial portion of this section of the tape is grainy, inaudible and speaker is far away from microphone]

Michael Baldwin: . . . And the functions that are used to implement this are like the previous as far as [inaudible] socket binding to a port, set option notification choices and then all the listen functions.

You call the listen functions [inaudible].

And then if we selected the notification choice of asynchronous notification, then you're notified of an incoming connection and then you use the "accept" function to create each connection, okay?

So it's like this list right here [inaudible]

M: [inaudible]

Michael Baldwin: Yes, sir, did you have a question?

M: [inaudible]

Michael Baldwin: The other thing that makes it hard is that the dynamic allocation of an indeterminate number of connections of. . . that actually. . . a C++ gives us nice mechanism [inaudible]

Even in MFC (Microsoft Foundation Class) you have a NDI parent that is really nice for doing the listening and then spawns an NDI child for every connection, which provides the framework for “X” number of children, which I like a lot.

The “accept” connection actually extracts the first connection in the queue of any connection, so a listening socket, for example, might be blasted with two or three connection requests and then the accept function is called for each one, all right?

So these [spawn] new, accepted sockets and the accept function actually returns as a unique socket [inaudible]. Then an object-oriented development environment helps manage the dynamic creation of. . .

A typical UDP session as we described earlier in the presentation is the same as far as creating socket and the notification situations, but as we learned, there is no connection. There is no connection involved, so there is a function called “send to” that allows you to specify the address and port where you want to send the packet to. I mentioned in the last [section] that a broadcast address can be used to send to all hosts on the physical sighting at the port specified.

So “send to” is different from “send,” because you have to specify the address and port of the destination.

And “receive from” is like “receive”, except that at point or two. . . you have to provide a location for the network address to be updated, so that you know where the UDP packet came from. So you have the address and port of the source; of the UDP packet.

Any software developers here in the room of Internet applications? I’ve thought about, well, what if I was to write an Internet application, sell it to everybody in the world or give it away and then send UDP packets. . . information on everybody’s hard drive or whatever. . . but on the Internet there’s nothing keeping something from putting that into an application.

Other people would go absolutely. . . go up in arms. . .

M: [inaudible]

Michael Baldwin: Well, I don’t know. I wouldn’t know about anything like that.

The “select” function is a blocking notification technique in that. . . I won’t give you the particulars on that unless anyone would like me. . .

I will introduce some miscellaneous functions here. Get [inaudible] name and give the name of the. . . and the address of the. . . at the other end of the TCP connection. You can get the address of the local name of the local end of the TCP connection. There are some options that you can query. The WINSOCK [inaudible] as well as setting options. You can do various levels of shut down; shut down receive, shut down send, on your socket. These are things that are kind of off to the side. Some utility functions called “HtoNL”, which is “Host To Network Line”, which helps us resolve whether or not it’s a big Indian or little Indian architecture on the host. I mention it just so that you are aware of it. INET-AdBR, changes a dot notation into a 4-byte address and INET-Net2 alphanumeric, changes a 4-byte address into a dot representation. These are just general utility functions that I provide as part of WINSOCK.

And here are some database routines, just to be complete. They’re not typically necessary or used, but they’re mostly included. . . the ones on the left, because the designers of the WINSOCK specification wanted to comply with the socket library. . .

[speaker just brought microphone closer and is now audible and clear]

Michael Baldwin: . . . to the greatest extent possible and since the UNIX socket library, on the left, provided those functions, they were rolled right into the WINSOCK specifications.

And remember, that the socket library was designed for BSD sockets on a Berkeley, how many years ago? I'm not sure; 20 years ago?

[Tape change]

Michael Baldwin: 13 years? That's a guess?

So they were reported over to the WINSOCK side and then the W-async functions were like asynchronous mechanisms for the same function calls. So [for] anything that the WINSOCK designers thought was synchronous blocking, they provided a non synchronous asynchronous notification.

The way all those work is that you provide the window handle and the message and then that window handle and message is called when that information is ready.

An interesting one that we use all the time is on the bottom, right "Get host by name", which is necessary in our library, so if I want to connect hp.dart.com, that has to be resolved into a Internet address, which may involve querying a domain name server, which may be over a slow link, like off a dial-up link out of your office onto some host someplace. So since that could take several seconds, it is a good idea to do something like that asynchronously.

Here are the remainder of the WSA functions. WSA startup — initializes the stack. WSA cleanup — uninitializes the stack. Some utility functions for getting the last error, set the last error. A question function — . . . is there a blocking function currently being handled? Set blocking hook, where you can install your own peak message loop instead of using the default for the handler, but all these issues only really come up if you're doing blocking calls and if you don't do blocking calls, then you have no need for these functions.

M: [inaudible]

Michael Baldwin: Yes, it does, and I don't know what you would use it [for]. . . the stack vendor would typically use it. So I can't think of a case where an application developer would want to use that.

M: [inaudible]

Michael Baldwin: "Set last error"?

M: [inaudible]

Michael Baldwin: Well, the way it works is that it's only valid really when you are notified that the error is present. So there's an event notifying you of the error.

"Development Environment, Section 3": The reason that I have this [is that] Section 3 talks about the different development environments because not everybody is a C or C++ programmer. In fact, as time goes on, fewer and fewer people are and more people are in fourth-generation languages like "Visual Basic" or "Adelphi" or these other. . . or what, sir? Or "Power Builder", there we go.

So in this section we talk about how you can get to the WINSOCK layer using those mechanisms. And I guess since we're developers of protocol libraries, that are in these environments already, I speak pretty intelligently to the problems associated with each.

M: [inaudible]

Michael Baldwin: The WINSOCK interface, which is a DLL, can be accessed, very conveniently, from any C-compiler, because they're structures that are often used for. . . and pointers to those structures, so that a function call, for example, like "receive from", requires a pointer to. . . a place for 6 bytes, so that the address in [the] port can be put in that buffer. So if you're in the Visual Basic environment, for example, you have to not only figure out how to make the DLL function call, but secondly you have to figure out how to provide a string pointer for that information to be inserted, okay?

The MFC supplies a C-socket class library, as the gentleman brought up earlier, and that library provides a thin wrapper around the WINSOCK function calls and has, as like a data member, a socket number and perhaps some other information. But it doesn't really add too much to the functionality or the limitations. . . or it doesn't compensate for the limitations of the WINSOCK layer.

From Visual Basic, it is difficult to use asynchronous notification and all of my customers that I talk to that have tried using Visual Basic against the WINSOCK interface have been doing it from a polling. . . a polling, non-blocking-type mechanism or polling blocking mechanism. But the real limitation of. . . of Visual Basic, after you get the data, is that you still have to implement an upper-layer protocol and Visual Basic, although it's easy to use, it's hard to bring to bear the structure, for example, to do an FTP transfer. There is a lot of coding that, although it can be done in VB, it is difficult to do a good job at it. Okay?

M: [inaudible]

Michael Baldwin: Yes, I'll introduce. . . some of those higher-level libraries in the next slide or two.

In "Adelphi", we just put together a Adelphi tool kit where we interfaced our DLL's into then. . . it was a challenge to establish that glue mechanism, but it can be done. And it can work with effort, but we still have to implement the upper-layer protocol.

In "Power Builder", we had difficulties integrating into Power Builder, because asynchronous event notification is impossible and if the gentleman back there can show me a way that you can get that in a Power Builder environment, I'd be happy to learn that. So you're trapped into a polling-type mechanism to check if something has been done or has completed.

Now [inaudible] can be constructed in "C", that provide a different interface. . . a specialized interface for you that eliminate some of these problems. For example, if you wanted to implement a polling mechanism, because there is a no-event-driven notification in your environment, like the Power Builder example, you could build. . . well, in "C". . . implement the WINSOCK functions and then have like a function that you could call, like once a second or something, to tell you something was done. So you could have all this activity generating in the DLL and then under Power Builder you have something set up where you call it [inaudible] or something like that, that function. And that can be done not too difficultly.

You've done this (laughter). Yes, you can have a wrap around the WINSOCK DLL that's specialized to what you want to do and then you can build all that and then have some kind of non-intrusive polling that is insulated from WINSOCK, but you can implement [it] like a state within your DLL. And check that. Okay, so, that's one approach. You can do that.

Another approach is to not use a DLL, but use a VBX or an OCX and in Power Builder, for example, we had a lot of difficulty integrating our VBXs into the Power Builder environment and it required a couple patches from PowerSoft, but it actually does work and we have a tool kit that integrates our VBXs into the Power Builder environment to do an FTP transfer or log onto a TELNET host or listen for connections.

So, VBXs are a way that the event mechanism. . . VBXs have an event mechanism built into them and it was kind of unique that that was the only way that we could integrate in any of our libraries into the Power Builder environment; because they had to support the event mechanism from Visual Basic. Because if they didn't, they couldn't claim to have VBX support. So that was a very powerful mechanism that we could take advantage of.

"Adelphi VCL Components"? You can create a DLL and then create a Adelphi VCL wrapper. I think it stands for "Visual Component Library", but it's a way that you can glue a DLL into the Adelphi environment and basically have the same thing that you have in the Visual Basic; a component you can drop on a form. Or you can use OLE components that can integrate WINSOCK into any environment with an OLE container. You know, today, there's, I think, Access. . . the data base language has support for 16 bit OCX. . . OCX's and of course Visual Basic, that was just released in September. Visual Basic 4 has support for OCX containers and we just started shipping our product this past Friday. We're 32 bit and 16 bit OCX'S or OLE components.

So these libraries all use WINSOCK and we'll introduce a couple sources here for components that provide value-add to the WINSOCK interface and by "value-add", I mean they can implement an upper-layer protocol, so you don't have to do it within your application. They have been tested, to one degree or another, on multiple WINSOCK stacks, so that odds are you won't run into upper-[inaudible] problems. For example, WINSOCK interface has been tested for a year and a quarter now in many, many different environments and since we've had the opportunity now to do that, we have very few problems with our libraries being run in any environment.

"DS Socket by DOLPHIN Systems" is a shareware component, has no run-time fees, like \$89.00 or something. You can have a license to distribute that with your application. "IP Port" is a similar type product and they provide an interface between the VBX and the WINSOCK DLL and various levels of other value-add. Both, for example, simply do a TCP protocol and provide a data stream. Whereas our product, for example, specializes in TELNET or FTP and Simple Mail and [Pop 3], so those are fairly simple.

The negative or the bad part about them is that there. . . the good part about them is that they are low cost or no cost. The bad part about them is there is little or no support. They can be found on the Internet and CompuServe, American Online; places where you normally download things in different levels of quality.

Yes, sir?

M: [inaudible]

Michael Baldwin: For the what kind of environment? "Imbedded environment"?

M: [inaudible]

Michael Baldwin: Well, any kind of imbedded application on this. . . the Pacific Coast, you probably won't find any components, because there's a very small market there.

M: [inaudible]

Michael Baldwin: You'd need the source code and there are some vendors that supply source code for TCP/IP stacks in the environment you're talking about.

M: [inaudible]

Michael Baldwin: Right. There is basically source code that you would have to compile for your target. . .

M: [inaudible]

Michael Baldwin: Fusion is one. Fusion. . . you should look in "Imbedded Software Magazine". That's where that type of thing is advertised.

Talking about commercial components? Commercial components cost money, but they provide some nice things like technical support. They usually offer more value-add with upper-layer protocol; take your pick. You buy the component for the protocol you want to implement and then technically it's plug-and-play. Samples are provided. [inaudible] in tool kits provide comprehensive examples. Tool kit costs range in the order of \$298.00 to \$698.00 and charge some type of user-based, run-time, licensing fees. And I'll compare and contrast those in a second.

Some offer fixed-fee licensing. So these are true, industrial components available from NetManage, for one. I understand they're out here. They are offered tools as VBX's as what I saw at VBITS in June, in New York City where they had just released them. They may offer OCX's, too. I'm not certain.

The only negative of their tool is that they require a licensing of the kernel, because their tools interface to a DLL and the DLL is only available in licensing as part of their kernel, so there tools won't work on Microsoft, for example, because it's not licensed that way.

So it's a technique to bolster their own product line.

[The Distinct] Corporation who is not here, they're my major competitor, and they call it their run-time extension. What it is, is a \$50.00 license, okay. . . so you build an application with their tool kit and then it's a \$50.00 license for every host where you host the application and it's clearly unsuitable if you have thousands of hosts that you want to put the application, although they'll, of course, negotiate a license. . . a user-based license and get the price per copy down.

Dart Communications, my firm, we offer three options and because of the three options, we do a lot of OEM-type licensing. We do have a run-time license, so we compete head-to-head with Distinct, although we discount it just a little bit as an incentive for us.

We have a distribution license [with] limited distribution and we have OEM partner subscription, that includes annual maintenance and support and that's the one where we really win; on the third one, because no other vendor offers a mechanism to update the library if there's a problem at one of our customer's customer location or environment.

Some final thoughts and then we've got a live Internet here, so we can actually run through some code and do a live Internet connection up to my home office in New York and we'll look at some of these functions and how they're called.

But, first, Internet software. . . great opportunities exist and when you [walk] floor here you can see. It's just an explosive market and there's more applications for it than software that's been written yet, so you know, if any of you are developing applications or looking at commercial applications or starting your own software company, it's just outrageous. It's terrific.

The WINSOCK interface requires a great deal of testing over a multiple stacks, so I just throw that out as a word of caution.

M: [inaudible]

Michael Baldwin: Yes, there is a company called "Stardust", yes. And one of the principals of Stardust was the lead architect for WINSOCK specification, okay, I.I.

M: [inaudible]

Michael Baldwin: Pardon?

M: [inaudible]

Michael Baldwin: A WINSOCK.DLL is the dynamic link library. . . is the 16 bit version that implements the WINSOCK specification, so. . . the specification is one thing and whether or not Microsoft sells it as part of Windows 95 or Windows NT or NetManage sells it as part of their environment or Distinct sells it, it's all WINSOCK-compliant and they all have their own version. Okay?

M: [inaudible]

Michael Baldwin: They are different products.

M: [inaudible]

Michael Baldwin: That's right. It's not an issue if you limit your product to a particular WINSOCK vendor. I'll make the point that I think Visual Basic primarily and Adelphi, secondly, is a rapid application development environment for implementing applications. I say that because I can write a VB application in two hours in Visual Basic and I can demonstrate one for you that took me two hours to write that incorporates all sorts of functionality. I gave it to my Adelphi programmer, who had to figure out how to do this in the Adelphi environment, and it took him three and a half days. Then I gave it to my C++ developer, who is a very talented, gifted, young man and it took him five days to do it in Visual C++. So. . .

M: [inaudible]

Michael Baldwin: I think it had something to do with the fact that it was Version 1.0 of Adelphi; the documentation wasn't up to spec. . . some work-arounds had to be accomplished. It was a new environment for my developer. He'd been in it for two months, but from his feedback, it was the combination of all of those things. But even after he explained that to me, I still think it would be a one-day-plus job for an experienced Adelphi developer.

Additional information: Richard Stevens of UNIX Network Programming, I use that kind of as my own big reference. . . big reference. . . on UNIX [inaudible]. Since UNIX is a host to TCP/IP, I use it as my de facto reference.

A second source: Internet site sunsite.university.north-carolina.edu and I did that from memory, so I think I got the right directory. I used to have it memorized for all my customers, but if I missed it by just a little bit, I'm sure you'll be able to find it; it's buried there in PUB. In there you can find all sorts of public domain. . . a WINSOCK source code. You can find the WINSOCK spec there. Information on WINSOCK 2.0. It's a great source. You might even see my tool kit there. Mr. Douglas Comer, he's got a series of [inaudible] protocol books that are quite complete and he kind of specializes. . . there's several in the series specializing in different areas like upper-layer protocols, WINSOCK and more basic stuff.

So, I am prepared to go through a sample here in Visual C++. We've statically linked in our libraries in debug mode, so I can show the functionality of a TELNET session. We can stop the debugger when particular things happen and kind of look at that.

Before I do that, are there any questions that I can address?

M: [inaudible]

Michael Baldwin: Well, I don't know. I don't know if a schedule is even relevant, because it just gets slipped. It's hard to come to standardization on thing like that, especially when there's no driving force; there's no big leader. It's like an agreement.

M: [inaudible]

Michael Baldwin: I don't know. I don't know. I'm not involved with it. Yes, sir?

M: [inaudible]

Michael Baldwin: Calls to the WINSOCK DLL?

M: [inaudible]

Michael Baldwin: All of our calls are to the WINSOCK DLL.

M: [inaudible]

Michael Baldwin: Let's see. I'd like to show one additional slide here that illustrates the question. This was a question that came up earlier and I failed to have this slide in that presentation.

Software Layer Support Productivity Tools and the gentleman had asked earlier about the standard OSI model here on the left, which starts from the physical layer at the bottom to data link network transport, et cetera. And how TCP/IP adapts to those OSI layers. With TCP and UDP in the transport layer upper layer protocols have traditionally been implemented right in the application. So if you got source code on an FTP client, it's available on any UNIX host, you'd see it's one, big application.

With our Power TCP libraries, we handle the session layer stuff and provide a special interface that implements the upper layer protocols. It can be thought of [as] occupying the session layer and below our product. Shown right here is the WINSOCK interface, so it's not exactly true. I'm taking a little bit of liberty pointing to this and saying it's [the] WINSOCK interface, because it's really not, but it's. . . the mechanism where our library or any WINSOCK-compliant application communicates with the TCP/IP service layer and that's documented as the WINSOCK interface.

Right here is any interface that communicates with the calling program and if it's a Visual Basic 3 calling program, and the library uses VBX, anybody's VBX that would be using properties and events. Or likewise if it's an OCX or if it's a C++ DOS library, that is where the user's class is and this is the class that is used as the base class that the user's class is derived from. Or if it's the DLL interface, then this is the DLL specification of the function calls within the DLL.

M: [inaudible]

Michael Baldwin: Well, we would probably, for the sake of our library it would make sense to be 1.1 compliant, because then we have a broader. . . then we aren't locked into 2.0. 'Cause 1.1 should be upwardly compatible to 2.0, at least that's stated in the intent of the specification, so we would leave things as they are, so that we would not interfere with any of our customer's applications in their interface.

M: [inaudible]

Michael Baldwin: You have to know it or you have to know the name of his computer; one or the other.

M: [inaudible]

Michael Baldwin: He does? Or somebody does?

Okay, we'll illustrate first one sample that with no security; no encryption in the clear, okay.

"SSL" which stands for Secure Socket Layer is a. . . I don't know. . . I know Secure Socket Layer is an encryption mechanism and I don't know what level it was built in. I don't believe it was built. . . I think it would be an encryption level before any data is passed into the underlying WINSOCK, okay?

M: [inaudible]

Michael Baldwin: Yeah, so it would. . . it's probably, you know, however that encryption is done, it happens just before it's submitted out the send function. You know, that's my understanding. Anybody can correct that. But a Secure Socket Layer is just a name for an encryption mechanism.

Now, this is an echo server that we wrote to illustrate the. . . how ports accept connections and there are about. . . in the Visual Basic version of this there are like 30 lines of code in the whole thing and out of that, there are about 9 or 10 lines of code that use our libraries, but what this echo server did as soon as I started it up, it started listening on Port 7 and this is an NDI parent form and there's a little C++ object associated with the NDI parent and what we're going to do is when I press this "test" button, there are five C++ objects, actually, right here: one, two, three, four, five and we'll make five connections to ourselves to Port 7 and after the connection occurs, we're going to send this data over the connection and then over here when every connection is accepted, we're going to dynamically create an NDI child window that will display the data it receives and then send back the data, so echo it back. Okay?

M: [inaudible]

Michael Baldwin: We're using. . . yeah, we're using a loop back to the same IP address. Okay, when this listener started listening on Port 7, it reported back what local IP address [it] is and then when we make the connection, we make the connection to ourself, so it's a loop-back mechanism. So it's routed down to the IP layer and then where it knows that it's going to this port on the local host and pushes it back up to the application and when we push "test" here. . . it happens very fast. Since this is C++ and [this is] a fast notebook.

On my 486 in Visual Basic, it goes slow and for Power Builder it goes very slow, because of the overhead, but if we close down a connection right here, we do it gracefully, so the other side knows about it and when the side right here is in [inaudible] we just, as visual cue, we close that down. We [inaudible] out the box. Okay, Connection 3 terminated.

So if we do a test, it closes them all again and opens them all again, okay? And if you want to send data, you know. . .

M: [inaudible]

Michael Baldwin: Yeah, this is a two hour app for me, okay, and obviously I am very familiar with our VBX libraries. This was, once I did this prototype, it was a 3-day project for my Adelphi programmer with two month's experience to implement it in Adelphi. After he had already created the DCL components, but he had to learn how to do the NDI child window and, you know, that stuff that he'd never done before.

Then my C++ programmer. . . I think it. . . by the time he was finally done and it was debugged to this level, it was probably five days, possibly four, but he's a very gifted and talented programmer, okay, and it was already. . . he was familiar with the libraries, so this is our. . . it's pretty cool. I use it as a demo, because it shows so many things.

M: [inaudible]

Michael Baldwin: Yeah. Let's do that.

M: [inaudible]

Michael Baldwin: This was myself, right here, this is a loop back, so I made connections right back to ourself.

The very nice feature about TCP/IP is they can be used for interprocess communication on your same host, so your application can run anywhere on the Network or on your host; it doesn't matter.

M: [inaudible]

Michael Baldwin: Yeah, I've got a UNIX host in HP, up in Syracuse that we're going to run through the development environment, which is kind of fun because it's pretty "live", so to speak.

So right here I have statically linked into my TELNET application all of our Power TCP libraries. And this is my window handler, right here that yesterday I had all sorts of interest in how this was implemented, but it's my window procedure that handles event notification, so. . . let's put a break point at two places; we'll put a break point at a "receive event" and "receive data". Then in our connect, where we call the connection function, we'll see what's implemented when we do the connect.

Here we go.

And we put the break point right there in our TELNET [inaudible] connect function, okay?

Now, we'll run this. . . TELNET application. . . and we'll connect up to our host in New York, so this is what it looks like. It's by VT-220, because it's got a VT-220 class in there. We'll connect up to my local host address which is my office in Cassanovia. We press the "connect" function and we're gonna launch this connect request with the remote host name.

Let me show it to you here. . . 204.7.222 to the remote port which is 23 and those are the only parameters that are being used at this point and we'll illustrate the. . . in our library, which is Power TCP connect function. We call this function here, which is the sync, okay? We check for the status and we're not. . . we are closed, so we're okay. Save the flags. We initialize the network and so first we make sure it's not initialized and then if there's no sockets. . . no socket count, we initialize the class. . . register the class, okay? Then we create the window, which is our event notification window. Then we create another window, also for putting in information and then we set the font on the VT-220 emulator, which will step over, implement the socket count, set the caption, do some housekeeping information here and we. . . check some licensing stuff, check the time.

Now, we're making our WINSOCK calls. We just called WSA Startup, okay, which put information in data and we have the local hosting which is something we found out hans.dart.com, okay?

Then we allocate some memory and we resolve the local name into an address for information purposes. That's an asynchronous call. More status information, okay, we initialized everything.

Then we change our state to connecting for defensive purposes. We resolve the address. Get the address event. We get some more information. We establish the sockets, so this is the socket call and the socket that's returned is Number 2. Set flags. We do the bind, which binds the socket to local address and, which is not specified at this point, we then do a select on the socket that we want to be notified of a connection event when there's data to read; when there's data to write and are closed. This select event selects the notification choices right there, so that we're completely synchronous.

Then we launch a connect request. I'm going to step through here synchronously, okay now, I stepped across it, come on, and it returns. So now it's armed. Now we're going to let it fly.

One of the problems with doing this and what. . . we'll run it again, only this time not stop it in the connect event. . . one of the problems of doing this is that if you're stepping through in debug mode, sometimes you can interfere with the communications timing, so this time we'll just hit F5, and let it go.

I think they disabled my Internet connection again.

Just to be sure. . . they did this to me yesterday, early. I don't know why.

M: [inaudible]

Michael Baldwin: I will, but if this thing is [inaudible]

I apologize. They did the same thing to me yesterday. They just turned off the connection. It was after the session. I've got no idea why they did this. It was operating correctly before we started.

Great. . .

M: [inaudible]

Michael Baldwin: We do. Let's try a. . . command line here. . . it's called Power TCP, yep.

M: [inaudible]

Michael Baldwin: No, we don't have a booth here. You can check our Website.

M: [inaudible]

Michael Baldwin: Yes. www.dart.com is where we upload demos.

M: [inaudible]

Michael Baldwin: Visual Basic is. . . you know, I'm sold as far as being a rapid development environment. It's terrific. And the event-driven nature of how the events are built right into the environment make it extremely easy to implement event-driven products, like communication's products.

M: [inaudible]

Michael Baldwin: Oh, Version 4 is. . .

M: [inaudible]

Michael Baldwin: Well, you know, companies like ours could come up with. . . start writing Java applications. You know, it's something we could start doing.

M: [inaudible]

Michael Baldwin: Oh, no, we could, but, no, we're not.

M: [inaudible]

Michael Baldwin: Not very much. You know, Java, you know, in the building of Java applets, it's different, totally. It's a new product area for anybody doing it, really.

M: [inaudible]

Michael Baldwin: It's basically hosting independent execution, you can run an applet on any host.

M: [inaudible]

Michael Baldwin: Well, thank you very much for coming and I'll hang around if anybody wants to talk about anything in particular. . . there are [the] applications; there are [the] data and enjoy the show.

TUTORIALS

VRML AND WEBSITE — 3-D ON THE WEB

SPEAKERS

Michael Roberts

President, Vannevar New Media, Inc.

Jay Williams

Vice President, Research & Development, Serve.Net

Michael Roberts: My name is Michael Roberts and this is the VRML Tutorial. If you're in the wrong tutorial, now would be the time to go. If you're in the right one, find a seat wherever you can. I think we're a little overbooked on this flight.

My company is Vannevar New Media. We've got some cards on the tables if you need to know how to spell that and a genuine movie poster to the first person who can say what the significance of our company's name is.

M: [inaudible]

Michael Roberts: Very good. You're an academic guy, though. You cheat us.

M: [inaudible]

Michael Roberts: Yes, indeed. Vannevar Bush was... Vannevar Bush was a science advisor back in the '40's and '50's and he predicted the Internet and the WorldWide Web. In fact, you can find a hypertext version of his article from 1945, about something that he called the "Memex" and I believe it was in *Atlantic Monthly*, but if you do a search on Vannevar, you'll find that article as well as a lot of stuff that we've done.

We're here to talk about VRML, which is "Virtual Realty Modeling Language." And the idea behind VRML is to create 3-D spaces on the Web. The Web is currently two-dimensional. Basically you're looking at pages; 2-D representations of data.

The idea behind VRML was to create a protocol that would allow 3-D environments over the Web. This involves some different kind of attributes and different kinds of considerations from those involved with HTML.

M: [inaudible]

Michael Roberts: There's a chair right there.

Before we get started, I want...with the details... I want to talk about the VRML vision.

Has anybody read either *Snowcrash*, by Neal Stevenson or *Neuromancer*, by William Gibson?

These are very good... very good fictional descriptions of where VRML and the WorldWide Web ultimately are going. And where they are going is a seamless, three-dimensional, immersive environment — a computing environment in which you are there. You exist there.

Now, let me read a little bit out of *Snowcrash*. And the reason that I choose *Snowcrash* is... and in a paper by one of the VRML developers, it says right here: "Goal: The ultimate goal of VRML is to model The Black Sun in Neal Stevenson's *Snowcrash*."

So we're going to take a little visit to The Black Sun and use this as a vehicle for talking about some of the issues surrounding VRML and where it's going, okay?

“Hero,” (the protagonist of the novel who’s name happens to be Hero Protagonist) “here is approaching the street” (and it’s all written in present tense, too). “Hero is approaching the street. It is the Broadway; the Champs d’Elysee of the Mediverse. It is the brilliantly-lit boulevard that can be seen miniaturized in backward, reflected in the lenses of his goggles. It does not really exist, but right now millions of people are walking up and down.” (So we’re talking about an environment that is complete; a “Mediverse.” Not only that, it’s collaborative. There can be other people in it at the same time.)

“The dimensions of the street are fixed by a protocol. Hammered out by computer graphics, Ninja overlords of the Association for Computing Machinery’s Global Multimedia Protocol Group” (that sounds pretty scary — there is a VRML working group that is hammering out these protocols. VRML 1.0 was released this past spring). “The street seems to be a grand boulevard, going all the way around the equator of a black sphere with a radius of a bit more than 10,000 kilometers. That makes it 65,536 kilometers around, which is considerably bigger than earth. So [inaudible] environment. So millions of people roaming around in it.

“Like any place in realty, the street is subject to development. Developers can build their own, small streets feeding off the main one. They can build buildings, parks, signs as well as things that do not exist in reality, such as vast, hovering-overhead light shows, special neighborhoods where the rules of three-dimensional space/time are ignored and free combat zones, where people can go to hunt and kill each other.”

Michael Roberts: Okay, so we’re talking about “virtual reality” as opposed to “real reality” and the idea of creating something where it’s not just a duplicate of what we have here. In other words, the object of VRML is not to simply take things that are in real reality and put them on “line,” but rather to put it in an environment where people can do things and interact in a way that you can’t in the real universe. See, “where the rules of three-dimensional space/time are ignored.”

“As Hero approaches the street, he sees two young couples, probably using their parent’s computers for a double-date in the Mediverse, climbing down out of Port Zero, which is the local point of entry of the monorail stop. He is not seeing real people, of course. This is all a part of the moving illustration drawn by his computer, according to specifications, coming down the fiber-optic cable. The people are pieces of software called ‘avatars.’”

Michael Roberts: An avatar is basically your representation in the virtual space that we’re talking about. The VRML 1.0 spec doesn’t really allow for avatars. It doesn’t really allow for the collaborative environment, but that is coming. Now, a company called “Worlds Incorporated” has extended VRML in a way called “VRML Plus” and they’ve created a collaborative environment. And Mr. Jay Williams will demonstrate that a little bit later. I have to leave early today. Unfortunately, I wasn’t able to change my flight, so I’m going to be leaving at a little after 2:00 and Jay’s going to pick up. And he’s the tech guy, so please give him a break on the visuals, he knows a lot about the technical side of things.

The World’s [inaudible] allows that collaborative avatar environment, okay.

“Hero cuts straight across the street and under the monorail line, headed for a large, low-slung black building. It is extraordinarily somber for the street, like a parcel that someone forgot to develop. It’s a squat, black, pyramid with the top cut off. It has

one, single door. Since this is all imaginary, there are no regulations dictating the number of emergency exits.

“Above the door is a matte-black hemisphere about a meter in diameter, set into the front wall of the building. It is closest thing the place has to a decoration. Underneath it, in letters carved into the wall’s black substance is the name of the place: ‘The Black Sun.’”

Michael Roberts: The Black Sun is a bar and a lot of the action in the book occurs there. It’s a kind of *film noire*, kind of place — if any of you’ve watched old Bogart movies. Okay, this is The Black Sun on the Internet. You can download this file and wander through here and you can see we’re approaching that meter there. We’re using a browser called “WebSpace” and Jay’s going to explain more about the features and details of WebSpace later, but let’s take a quick tour of what we’ve got versus what the vision is.

First thing you notice is that the polygons that represent The Black Sun, are getting a little squirrely in the rendering here.

VRML currently, although it’s “Virtual Realty Modeling Language,” really [should be] Virtual Realty Rendering Language. In other words, it’s not really modeling anything; it’s simply rendering surfaces. And because those files have to be very small in order to transfer over the Internet... remember now, graphic’s files traditionally have been very large. Because those files have to be kept very small, you can’t have that many polygons. You can’t have that fine of structure on your models, so you see some things like this.

Now, we’ve got some other models. Now we’ve just gone straight through the wall of the... of The Black Sun. And this is the interior. It is extremely simple. This is a very simple model. And we’ll show you some more complex ones later, but there is the entrance, right there.

Okay, so the question is: How do we get from that vision or from here to that vision? What kind of things are missing in our virtual realty world?

Well, right now, it’s strictly visual. In other words, you’re seeing surfaces rendered. What kind of things do we need to add?

And I’d like this to be a little interactive and let people kind of... what do we need?

M: [inaudible]

Michael Roberts: We need sound.

M: [inaudible]

Michael Roberts: Some text.

M: [inaudible]

Michael Roberts: What other things basically make up reality? In other words, if you’ve got reality when you make virtual reality...

M: [inaudible]

Michael Roberts: The ability to manipulate objects. That’s an excellent one. That’s an excellent one.

M: [inaudible]

Michael Roberts: Where are you? Orientation. You've got to have a way of knowing where you are.

In the browsers there's usually a couple of different modes where you move through the space; one is this walk mode and the other is an object mode. In the walk mode, you're kind of looking at the overview of... you're kind of feeling your position in the space and in the examiner mode, you're actually going to be manipulating an object. Let's go. Yeah. And Jay will explain more about that later. But those are the two modes for orienting yourself.

But there's got to be substance. There's got to be more to this and that's where the future specifications come in. That's where VRML 1 etc., VRML 2.0 come into play. Okay, we've got to have some way of getting from our simple rendering system to a system where we can interact.

Now what kind of applications would there be for VRML? In the book it's a meeting place. It's a social gathering. It serves the same purpose that any kind of location serves in the real world. The difference is that anybody can get there, right? If you create a virtual space on the Web, anybody can get there who's on the Internet. If you create a physical building, in reality, you've got all the physical barriers to travel...to deal with and that brings up the point about virtual reality, not simply being a duplication of reality...and here's an example where I wish I was in a VRML environment right now. We want to make it better, okay.

The ultimate goal is to create a room just like this; where we can interact exactly like we are now. Where I can look into the faces of the people I'm speaking to and I can chat with them after the show and we can have an actual dialog, but I could still be sitting in my office in Houston. That's the objective. Save myself the \$400 plane ticket and the miserable ride that I'm going to have back and do it from here. Not only that, but it allows a lot more people to attend. Okay, there could be a lot more people here and I could probably do a lot more sessions.

We've got physical limitations. We've got people standing up here and they're uncomfortable and they're saying, "Oh, God, I wish I had a chair," and it's going to disrupt their concentration by the time this thing's over, because two and a half hours to stand is quite a long time. On the other hand, if you can put your goggles on and sit down in your comfortable easy chair with some nice music listening in the background while you wait for things to happen, it's much, much more convenient for you. Okay?

Now, that doesn't mean that it isn't going to be active and isn't going to be engaging, because I can do the same things in the virtual world that I can do here. You know, if I see somebody nodding off, I can say, "Wake up and pay attention to what's going on."

He's going, "He's pickin' on me."

No, it's very unfair. He's paying attention.

But the point is that the VRML environment offers a lot of promise for the future. What you're going to see here is maybe a little disappointing to those of you who are expecting The Black Sun and Hero Protagonist to go in and have sword fights, but that is coming. And the point is that it's started now. You are in at Ground Zero. It just came out in April. Okay, we're in on I.O. We are where the Web was two years ago. And just think about how the Web has exploded since 1993. And then imagine how VRML is going to explode in 1997.

M: [inaudible]

Michael Roberts: Well, first of all there...it really isn't too bad. You can get some fairly-decent models and some very low [inaudible] and let me take this opportunity to show one of the more interesting ones.

M: [inaudible]

Michael Roberts: Okay, can I dig this down here? I just want to go over to... okay. I want to go over to... this is the castle, right, yeah.

The file you're about to see is a 50K file. It imparts quite a bit of information. It's an interior of an Italian castle. On the other hand there are models out there, very nice models, some of the best models I've seen done by a company called Lightscape, that take up like 12 megabytes. The bandwidth issue is everybody's issue and not just VRML's.

M: [inaudible]

Michael Roberts: Yeah and there are a whole bunch of proposed solutions from AT&T's new system of driving ordinary phone lines up to God-knows what kind of bandwidth to fiber-optic cable to the cable companies. The cable companies are talking about set-top boxes.

So the bandwidth issue, I think, will be resolved about the same time that this converges as a useful utility. Right now, even if everyone had the bandwidth, I seriously doubt a lot of people would be using them now. Because it's not interactive yet, with the exception of the World's [inaudible]. And even that...it's kind of cool, but there are some limitations. There's some development to be done.

M: [inaudible]

Michael Roberts: Okay. There are some neat things that you can do, but as far as the average person and doing what I talked about which is using it for conferences and things like that, it's still a little ways down the road, I think, for most people.

This is the interior of an Italian castle on the Internet and it shows that... one potential use, which is educational. You could very easily imagine a representation of a museum on here and, in fact, there are some, in which a school that couldn't afford a field trip, could at the same time, at least get the feel of going through the museum. Okay, they wouldn't get the complete experience. I'm not here to tell you that VRML is going to replace your real experiences, but it's going to give them an opportunity over and above what they had. It's better than nothing. And this is an example of how that might happen.

Now, this is the "walk-through" mode, again.

M: [inaudible]

Michael Roberts: Yeah, this is a handlebar control and when I push forward, it moves me forward; when I drag to the side, it turns me. It's just like a handlebar on a bicycle.

M: [inaudible]

Michael Roberts: Yeah. This here is a "viewpoint" control, which the WebSpace browser uses and notice that when you do it, you're looking at a screen there.

When you do it, it moves you to the new viewpoint. You can control pretty set viewpoints along the way. It can be very handy for a museum kind of application.

Okay, that's an example of a "walk-through" kind of application. This was only a 50K file. Let's take a look at... let's go ahead...I think it's this one here...yeah...this is a great little educational application. How many people here have ever tried Origami? Okay, a few of you.

How many people have done Origami out of books? Okay, it's not easy, is it? Because you're trying to figure out what's happening in 3-D from a 2-D representation of it and no matter how many little, dotted lines and how many different little codes there are for moving the flaps of the paper around, you can't figure out what the thing really looks like. You're saying, "My God, I wish I just had somebody here who could show me what that model looks like."

Well, now you do. On your desktop. You've got somebody who can show you each step and what it looks like when you're going through a model... on your Origami model.

M: [inaudible]

Michael Roberts: Okay, are we there? Yeah, pick a model that's working.

Go ahead and use the world, the manipulator and kind of show how it...okay, now you can see this is the "examiner viewer." This is the other mode that I was talking about that we use as individuals when we're interacting with 3-D space. One is to move ourselves through that space and orient ourselves in the space; the other is to manipulate objects in the space that we're focused on.

Now, here's a piece of paper folded with the first fold of the model. Now, if you click on that and you can tell in VRML when you can click on something, because it lights up. There had to be some kind of way of giving you that clue and that was the way they chose. It lights up and you can click on it and it'll go to the next fold. And so you can go through each process and make sure that you're doing exactly what you're expected to do in order to achieve the result or to finish the model. And for anybody who's used the 2-D version, this is so much better... so much better for doing Origami. And there are a lot of applications like that. You know, fixing your car. They show you in the book where the thing's supposed to go, but they don't explain to you how you're supposed to get the piece through all these other things that are in the way and then try to get a screwdriver in there as well...it's really important, the 3-D relationship can be put into VRML and made available to thousands of people.

Now, modeling techniques and three-dimensional techniques have been available for PC's for a long time; the difference here is that now you can make it generally available to literally millions of people. You don't need a new kind of server. The VRML files can be served by any Web server, okay. There are a number of new browsers out there now that are freely available. So, this is something that is happening now, and the only issue is the quality of the models and the quality of the content. The technology is here, now it's up to folks like us to develop decent content that people want to see and use when they're out there.

I am gonna have to go here, shortly. I did want to take any questions regarding how VRML fits in...you know, kind of philosophically to the Web.

Yes, sir.

M: [inaudible]

Michael Roberts: There's a distinction... there are two technologies on the Mac: One is QuickTime VR and the other is QuickDraw 3-D. There is a VRML browser, based on QuickDraw 3-D for the Mac; it's called Whirlwind. Quick...

M: [inaudible]

Michael Roberts: Yeah, QuickTime VR is another technology... how many people here use Mac's?

Okay, quite a few, so this is worthwhile.

QuickTime VR is an extension of the QuickTime protocol wherein it creates the illusion of 3-D. It puts you within a shell of 2-D images. If you've ever seen those panoramas. You know, you walk into a room and there's pictures all the way around you. That's what QuickTime VR is like, except that as you get closer to the picture. It gives you another shell to look at, so it creates the illusion of a 3-D environment. It's actually very convincing. It can be quite good, but it's not true 3-D.

Yes, ma'am.

W: It's probably a stupid question, but if you have a VRML browser, does that do everything else in the Web as well?

Michael Roberts: If you have a VRML browser, does it view everything else on the Web?

The VRML browsers that are out there now are add-ons. They're helper applications or plug-ins and you'll need...

M: [inaudible]

Michael Roberts: Not at this point. I don't think any of them are independent.

M: [inaudible]

Michael Roberts: Worldview is? Okay, if you use Worldview then it would also be a Web...

M: [inaudible]

Michael Roberts: Yeah. Yes, sir?

M: [inaudible]

Michael Roberts: I don't think it'll supersede it; I think it'll be incorporated in it.

Remember what we were talking about is modeling the world as it really is. In order to do that, you've got to get beyond static pages, static worlds. Right now VRML basically describes a protocol wherein you can create a static environment. It's a scene and it's called a "scene." Okay, things don't happen in that scene without some kind of dynamic actor, some kind of action and in order to have an action, you've got to have some kind of program. You've got to have something going, cranking, and Java will probably be in there. It's wide open right now, but I suspect that Java will probably be incorporated with VRML.

Yes, Sir?

M: [inaudible]

Michael Roberts: Yes. Yeah, *Lawnmower Man*? Did anybody see *Lawnmower Man*? Okay...

M: [inaudible]

Michael Roberts: Yeah, in fact there are some experimental...and yes, definitely. The idea is that you'll have three-dimensional ways to interact with data, kind of in the same way you do now. I mean, you've got your file cabinet. You don't have to literally spread all your papers out on the floor in two dimensions and pick them up; you store them in three-dimensional environments and reference them by a three-dimensional system, which is your filing system, typically, in the physical world.

M: Is this model physical 3-D that you put in World or is that something that's just adjustable?

Michael Roberts: Let me run that...

M: What I see so far is a model of 3-D you put in perspective World; is that built into the language?

Michael Roberts: Yes.

M: Okay.

Michael Roberts: Yes.

M: So I can't go to something... a different type of geometry?

Michael Roberts: There are extensions in VRML or in...okay. He's asking about the geometry. I don't think I've ever seen one...

M: [inaudible]

Michael Roberts: Okay, they're going to look at an alternate geometry.

M: [inaudible]

Michael Roberts: Basically most stuff is based on X,Y,Z and rotations about 3 [inaudible] for 6 degrees of freedom. And you're talking about...

M: [inaudible]

Michael Roberts: Could be ignored...they could be ignored. And apparently they are in some of them. Okay.

M: [inaudible]

Michael Roberts: Okay. One more question. You had one, didn't you? Okay.
Any others? One more.

M: [inaudible]

Michael Roberts: Right, when you're viewing a scene and you're manipulating it, that's running locally and that's the whole idea, is that you download the whole model, with the exception of what's called the "WWE In-line" command, which allows you to reference another server.

Just briefly, if you're in a world and you only want to define kind of the entry point, you can reference other worlds that are out there or other scenes that are out there using this in-line command. And then when you go to that home world or you go to that initial starting point, as you get closer to the edge, it can load that in-line, so you can have sort of a seamless transition from one world into another. And that's what makes it so exciting. That's what allows the creation of this Mediverse, which can be a patchwork of everybody's VRML world or home scene, I guess you'd call it.

Okay, I am going to have to catch my flight. I really appreciate you all being here. If you have any questions or comments, you know, e-mail me. I'm in Houston, Texas, but I get out to shows a lot, so please get in touch. Thanks very much.

M: [inaudible]

Michael Roberts: Mike@vannever.com. I've got cards and I'm going to leave them up here.

Jay Williams: Also, if you have anything else that you need to get a hold of Mike about, I can give you all the necessary information. Hopefully I can answer most of the questions, so I don't think they'll be too much.

Michael Roberts: And we have some packages here. We have some packages here for you, too, so don't forget to get your packages.

Jay Williams: We have a whole suite of materials which we will be handing out. I'm going to go through what some of those materials are so they can make some sense.

Now, the amazing transfer of the mike. This is the one technology I've never been fond of.

Well, my name is Jay Williams and I'm the Vice President of Research and Development for a company called Serve.Net in Los Angeles, California and Houston, Texas; two offices. We do high-end server, home page and other technology design, mostly for the movie industry, but also for other folks.

I'm basically going to go through some of the stuff that Mike breezed through very quickly. We're going to talk a little bit about the history of VRML, then we're going to talk about the technology of VRML, looking at SGI's products running on the Indy that we're running on right here and also talk about other platforms and what the parts and pieces are that are available. I'm going to try not to fall apart. Hopefully that will work. I assume they'll come tell me if it doesn't.

In terms of history, Mike had mentioned that it's brand new and it is brand new. April really was the spec 1.0 finally agreed upon. There are a lot of parts to the specification. We're not going to go through all of them. I have a detailed copy of the specification for you in the handout materials, which we actually have enough of, I think.

VRML is a vision. Mike went through some of the visionary pieces of it. Since he's on the graphic side and I'm on the technical side, I have a little more hopeful... useful pieces of it right now. I don't need to build extremely high-end graphic pieces, but I need to get concepts across to users, so using the simple polygon model, you can actually do quite a bit and we'll see quite a few things that are going on here.

From a hardware standpoint .

M: Thank you very much, sir.

Jay Williams: Absolutely. From a hardware standpoint, our hardware has now reached a point to where we can actually do some useful rendering. And we're going to talk a little bit out "rendering" and what that means and what it is in terms of the desktop work station.

Currently there's a limitation of how many polygons you can draw. Most of these, as you'll notice, even though we're talking about them as polygons, they all show up as triangles. The reason why is the triangle, from a mathematical viewpoint, is the quickest and easiest to draw, so more complex are drawn by actually creating the triangles.

When VRML was originally thought of, by several people: Mark Pesce, who wrote this text, which is in my humble opinion, one of the better texts available on the subject, which is *Browsing and Building Cyberspace*. Also our hosts, Mecklermedia, have a new book out which I have not had a chance to review yet, *VRML in 60 Minutes*. I suspect that...yeah, there's a copy of the *60 Minute Guide to VRML*." I'm always a little nervous about those particular things, but I assume that it is fairly good. One of the people that wrote it, [Sebastian Hassenger] is really active on the mailing list and things, and so he's certainly up to speed on the information that's out there.

Mark Pesce actually decided on his own that he wanted to do this kind of thing, so he enlisted the help of a person named Tony Parisi, who is a friend of his and they put together an original browser, which they called *Labyrinth*, which was in '94. It was... is that right? My dates sometimes get confused. It's all moved so fast. I've personally been working on the Internet and doing things with the Internet for almost ten years, so in dog years that's about 100,000 years.

But as they decided and got good at doing this, it was actually shown to some other folks, [Tim Burners Lee], most importantly, who invited them to come to the International WWW Conference, the first one, and deliver a paper on the subject.

Well, as you can imagine, it was quite revolutionary to see a yellow banana on a screen and be able to click on it and go to a home page. So that's a new concept in terms of hypertext.

From that original thing, many other people got involved; people from SGI; people from OKI; people from other corporations who were interested in the technology. One of the reasons that the technology has moved so far and so fast is because the companies that are involved have a very vested, commercial interest in making the technology available. So much so that SGI was persuaded to make a huge, commercial product that it had, *Open GL*, available to the public domain. One of the things that was very hard, anytime when you're doing a specification, is to actually get the things... the code available publicly for people to share it, because it is very hard to get developers to participate and work on programs where they don't have access to the particular code that they need.

So in order for the project to be successful, they believe that they had to have open code; that everybody could see the source and understand how the products were developed.

SGI has had a product which has been very successful. You've seen the results of it in things like *Jurassic Park* and other movies that have had lots of animation and especially mapping to create like the dinosaurs, for example, in there.

Also things like *Lawnmower Man* and things like *Terminator 2*, who also used that same technology. That technology is called Open GL, Open Graphics Language. And it's used by lots of different rendering engines. It's used by lots of people for different things. The product that is involved... that it is actually marketed as is *Mentor*. I'm sorry, *Inventor*, which the text, which I have floating around here, is called *Inventor Mentor*. That's why I said that, which basically gives you an overview of *Open GL* and how the pieces and parts work, along with the *Inventor* tool kit.

When they did the *Open Inventor* subset, they included everything that they thought they would need, at least to get the spec under way. And they did a very good job of the pieces that became available. We're going to go through in a minute and talk about what it takes to make a 3-D space, in terms of lighting.

How many people here actually work in 3-D environments? Do any kind of 3-D development type of stuff?

Yeah, we're going to spend several minutes on going through what those kind of things are, because it's important to understand what it takes to make up a 3-D space, because if you really haven't thought about it, you'd be amazed at some of the things that are involved: lighting, for instance. You know, if you don't have any lights, everything appears black. And, you know, it's very hard to understand some of those concepts and we're going to see how some of them work in the browsers and how you can actually determine how the textures appears in those types of things.

So after the conference, these folks got together, including the people at SGI and they began to work on new browsers. The project was sold to SGI and they began development on *WebSpace*, which is the navigator we see here, which is the most advanced of the navigators available.

Now, the reason that when I say... when I define "advanced," I mean "advanced" in terms of features; in terms of extension ability; in terms of the integration it currently has.

Now, to make things a little more confusing, another company comes into the picture, which is known as TGS, Template Graphics Software. The reason that's important is because most of you probably don't have SGI work stations. How many people here have SGI systems?

Yeah, I suspected that. How many people are on Macs? And how many people are on PC's, NT, Windows, those kind of things? Anybody else on UNIX? Other UNIX flavors? What are they?

M: [inaudible]

Jay Williams: You name it? Okay, I'm used to that one. Solaris? Okay. All right.

Any DEC folks? Okay, good. I just want to get an idea so that I... just to check so that I can tell you which browsers are going to be available and when. I have some insights as to where they are in the development process of different platforms.

TGS has the rights to market the *WebSpace* product on every other platform except SGI, so anytime you use, for example, the Windows version, which is by the way available, the Win '95 version is also available, the 32 bit... you're going to be getting those from TGS and you're going to see their name as you drive around to some different places and things.

M: [inaudible]

Jay Williams: It's, at the moment, it's shareware. It's downloadable with a price to be announced. I don't know if they officially announced the price yet.

More importantly their in-line browser, which we'll talk about in a little bit, that is a plug-in for *Netscape*, is going to be available real soon now. I have the beta and we should be out of beta... they're racing very fast to get out of beta, so very soon.

M: Is that shareware, also?

Jay Williams: They will all have a price attached. You'll be able to download the plug-in and pay for it like you do most other things.

Seriously though, I think it won't be a huge cost as far as viewers go.

Currently *Web FX* from Paper Software is available for *Netscape* 1.X products and they're 2.0 product is in development as well. It has one small bug to be fixed. There's always one.

But bear in mind that in *Netscape 2.0*, is very, very, very, very much still in beta, for any of you who use it extensively, you will know exactly what I mean. Getting rid of cached item No. 93. That's a favorite error message these days.

But in terms of the history of the project, many other people have stepped in to do things: Tony Parisi, who is one of the original creators of the concepts of things has formed a company, Intervista Software and they market a program called *World View*. That program takes a little different approach. As we've been looking at the *WebSpace* browser, they have the joystick approach for moving through the world. And while the joystick approach is a good approach, it's not necessarily the best approach, depending upon what you're doing. The *InterVista* product, which runs...there's a UNIX version... I guess there is a UNIX version, but I haven't seen it, but it runs on Windows '95 NT and is actually shipped on the disk. There's a CD-ROM that comes with the *VRML: Browsing and Building Cyberspace*. And we'll talk about a lot of the tools that are included in there, because there are some very important tools that are included on that disk along with some models and other things. And the book actually has a tutorial that let's you create a model of the solar system, which is pretty entertaining. It actually creates a clock. It's a pretty good model. I'll talk a lot more about interactive things, because I have... Mike works a lot with NASA and different people that develop extremely intense graphics for modeling space projects and things like that and whereas you can't necessarily bring a 150 meg model out across the Net, there are a lot of things you can do with smaller models.

Anyway, so there are several other products and we'll talk about them as we go through them. Those are the viewer products.

More importantly, though, are the construction products that let you actually build things. Just to shock people, we'll go look at one of the larger sights and then I'll actually show you the code that makes it up.

For example, as we were looking at it, you saw me driving around through this sight. You can see that this sight is extremely intensive. It has a whole lot of different things in it. You'll notice all of the objects inside. You can see that it consists of a whole lot of parts, both interior and exterior. We can move through the model piece by piece. This is one of the models that the people from *Lightscape* built much more extensive models than this one, but as you can see it has a ton of different objects inside of it.

If we were to go up, for instance, and say "view source," you can see that the source is pretty extensive and we'll go through what some of that is. Please note how slowly the scroll bar is moving on the right of the screen. Okay. Should you even have to attempt to write this, your arms would fall off before you were done.

So, how do we get around that? And, you know, "VRML is just a text file."

Well, yet, it's just a 10,000 line text file, so what happens is you use modeling programs to create the actual environment then you can go in and hand-code some sections of it if you want to change how some of the environmental rules work or you may find out once you've created your original model, that frequently some browsers will look at things a little bit differently and so you may want to modify some of the original settings that you used.

The good news is: You can use your traditional programs that you're used to using. If you're used to using things like *Renderman* to create 3-D objects. If you're used to using, you know, *3-D Artist* or any of the other programs that are out there that you like to use, almost all of them have either a converter available so that you can convert those models. They can export it to a particular format and you can use a converter to convert that model into a VRML. Several programs have actually gone further than that and incorporated a VRML export function into the actual program.

Two programs are included on the VRML desk. One is *Home Builder* which is a very simple program for creating space. It's job is to create walls, doors, windows and the outer

sections of things. It doesn't truly create objects, though. The other program is *Walkthrough Pro* which the program on the disk is *Walkthrough VRML*. It has a VRML export function. It can create objects. It comes with [Brutes]. You can actually see a small representation of a character very similar to Brutes. Brutes is a human object. And you can see an example of Brutes there. It's very similar to that.

Now, as we were mentioning earlier, many of these objects and some of the interactive pieces that you can do, is create links. As you see when these different things light up and we've been going through, you can make actual hypertext links to objects.

With the things that we're talking about, you're going to hear me say, "In the *VRML 1.1* spec," which is actually under discussion and things are going on now and I'll show you some pointers to the places where you can go find out information and, in fact, I've included several papers from the working group on *VRML 1.1* that talk about the important things that everybody listed when Mike asked for things earlier: audio, manipulative objects. In fact, I'd like to take just a second and answer a question that was asked earlier about the relationship of Java to VRML.

I heard the same comment out on the floor yesterday. Somebody said, "VRML? Oh, yeah, Java will do that. We're just going to incorporate that."

Most people don't understand what VRML is in terms of modeling. Their view of what Java is going to do is that it's going to do still-level animation. Okay, we're going to take 30-frame pictures and we're going to use a program to flip through these 30 frames. You know, I gave up on those flip books when I was about seven, so I've got to have a little bit more... a little bit more tech involved in what I'm doing rather than just, you know, flipping through a 30-frame animation piece. And this is much, much more sophisticated. I mean, there is no comparison between what's going on here.

Please understand that what's happening on the machine that we're looking at here is it's taking a set of commands and actually re-drawing the a-polygonal shapes, the representation of the environment we're looking at here. Okay, the difference between that and a flat picture is radical and the differences between what you can do with Java combined with this technology is radical. What you can do is change the environment based upon user input. So, in other words, the more important combination of how Java and VRML are going to work together is that we could, for example, click on Brutes and he's going to turn around and ask us where we want to go

[Tape change]

Jay Williams:... to integrate with the visual drawing capabilities.

Yes, sir?

M: [inaudible]

Jay Williams: There are a lot of people who work on a lot of different things and one of the things that I'm working on is trying to make Java, *Netscape* and the viewers all behave and work and create integrated things that will use them. My company works a lot with folks in Hollywood, and so you can imagine the urgency that people have there for us to create that kind of thing to where Mickey Mouse can walk out and actually shake your hand.

M: [inaudible]

Jay Williams: I would say not far. "Not far" being defined as a couple of quarters. You know, it's one of those things that depends on time and who pays for it. You know, it's customer demand that's going to create those kinds of things. You know, I'm driven a lot by market forces and so luckily what I just described is something that I think that market wants as soon as it can get. And I see lots of opportunities, you know, for that happening. And there are a lot of really great programmers that are interested in doing those kinds of things and so with the collaboration things that have been going on, both historically and currently over the Net, I don't think it will take anywhere near as long.

If anybody had said you can get a specification now for a 3-D modeling language across the Internet in less than 12 months, and told me that 3 years ago, I'd of said you were insane, because there's no way, but because market forces are driving the growth of the Web and the growth of those technologies, you know, we can do it as fast as we want, so to speak.

Now, there are some limitations and we'll talk about some of them as we go through. One of the other limitations that things like Java will be very good for solving is the physicality or the physics problem. One of the biggest problems right now and if you go to WorldChat or any of those kind of things, you're going to find out there's a etiquette rule on WorldChat that says, "Please don't walk through someone else's avatar."

The reason for that is because there are no boundary descriptions. There's no way for your particular avatar to know another avatar is physically there. So you don't have any way to stop yourself from walking through a wall or stop yourself from walking through another person and those kind of things. That's the physics component. And just the simple lack of that, by the way, means that you can do non-Euclidean kind of things that you wouldn't normally do in a physical universe.

So we're already living in a world that's not exactly representative of that particular set of physics. So...and you'll see it happen here as we go through a wall or those kind of things. You'll see that I'm just careful to drive in the lines, so to speak. You can certainly drive outside of the lines.

So, in terms of adding that physical dimension to things, that's coming down the pike. I'm going to go through a list of what's on the immediate I.I spec that people are working on right now. Also at the top of that list is "audio." I'm a very big proponent of having to have an oral component to do the type of work we're doing. Not to mention I like to hear things, but I think it's very important for giving it some life. You know, especially moving around and looking at different worlds and areas.

So, that's pretty much the history overview, briefly, with a few technical things thrown in. Are there any questions on history? Just in general where it came from? What we're doing? Platforms? Technical things?

M: [inaudible]

Jay Williams: Oh, it's world.com. www.world.com We'll actually see it if we have time. I'm going to do that last, because that can take up a lot of time. Oh, look, there's Nicole Simpson's avatar. Yes, sir?

M: [inaudible]

Jay Williams: Not yet. It's in the discussion stage. It's been going on in multiple places now. We have a mailing list... there's a Wired-hosted mailing list where all the serious technical discussions...

M: [inaudible]

Jay Williams: Yeah, there's all that [inaudible] but it hasn't been moved over to Comp yet. It's still in the discussion stage. To get it moved over... you know how the NewsNet sometimes takes a while to get things moved around.

M: Do you know if that book is available at the show tomorrow?

Which one? *The New Riders*? You know, I didn't see *The New Riders* anywhere. Has anyone seen them anywhere around here; *The New Riders Publishing*.

Yeah, I don't think so.

M: [inaudible]

Jay Williams: Yeah, the *Pesce* book. Is it out anywhere? I haven't seen it anywhere at the show. Bookstar, Bookstop, all those places have it. It's pretty widely available... Barnes & Noble.

M: [inaudible]

Jay Williams: Yeah, I'm going to go through what they... it actually comes with a virtuous VR program for Windows and the Mac. It doesn't come with any browsers for the Mac. And we'll talk a little bit about the Mac. I think there's a lot of Mac people here, so I'll spend a few minutes talking about history of VRML and the Mac, which is a little different from the rest of the world. For a lot of reasons.

M: You mean Windows 95?

Jay Williams: I mean... some things are... any 32-bit Windows is what I'm talking about. So if you have Windows 3.1, you can actually load the 32-S stack with it and run most of the application. There are a few things... I will tell you now: It's going to misbehave horribly. Especially if you start working with an *Open Inventor* piece or something like that. It won't run... you'll...

M: [inaudible]

Jay Williams: Yeah, it's time to upgrade. There's not much... no way around it. Please get 24 meg RAM. I don't know how many times I've had to deal with people saying, "It's crashing my machine!"

Well, no, it's just slow.

M: [inaudible]

Jay Williams: Yeah, actually that's a good question.

WRL is the World format. It's a text file format. You'll see the example in the *Pesce* book that actually takes you through typing in the sections of it. So you'll actually type a model in there. I confess, I have typed almost no models other than the one that's in that text right there. Simply because it's too strenuous. And there's no reason to. With any of the modeling programs that are out there, you can model quick polygons and do things fast. One of the things were going to show you is the brand new, two weeks ago released program, *WebSpace Author*.

WebSpace Author can very quickly create all of these different things that we see here. It can actually move and reuse objects. But before we go into the authoring pieces, I want to talk about things that are available out in the Net and kind of what the conception of how things are going to work are and why VRML, not to answer the Java question again, but why VRML is very different than the things that are going on with that.

First of all VRML, like Java, is object-oriented in concept. You create objects in the virtual worlds, okay. These objects are reusable objects. For example, if you buy one of the sets or even one of the ones that are on the CD that comes with a suite of tools to do things like... that you will always use in modeling: a couch, a table, some chairs, you know, wallpaper, you know, the kinds of things that you would use for different things. Those objects, once created, can be extensible and put out on the Net. Even copyrighted, so that people could create special chairs or special different objects: cars, trucks, roads, cities, mountains, all kinds of creations. Using the things that are already contained in the spec, one of the particular pieces of the specification is what's known as *www.in-line*, which is actually an anchor, just an HTML anchor to point to another object. That object does not need to reside on your machine. That object can reside anywhere. And we're going to look at one of the repositories of objects, where all of the basic geometric shapes are already modeled there.

A lot of basic, different pieces are there. There's even some really wild pieces that are modeled out there that you can actually use, without even having to download; you just point at the other object and you can use it directly in your particular world model. You don't need to have that physical object here.

In addition, several things are being discussed. One of the things, obviously that's been very hard to get around both in HTML and VRML is the local disk problem. In other words, being able to actually, because there are so many different file system constructs, having a way to reference files on a local disk, read CD-ROM, so that you could distribute heavy-duty graphics out to a particular thing. For example, you can build almost anything with about 2,000 geometric object shapes, okay. If you had a CD-ROM containing those shapes and you were to distribute that, then loading time is insignificant. Bandwidth is insignificant. Content is everything at that point and it doesn't matter whether you retrieve the content off the Net, knowing that you have this model on your local drive.

So if you think about the ramifications of an environment like that, you can see that the opportunities for doing things, both commercially... I mean, as a designer, I think we're going to see people who's job, just like there are people today, who design particular animations or particular furniture, or particular things. There's going to be an actual virtual object design job out there. You know, I can't draw stick figures. Give me a marker to draw on the board. Network diagrams are about as far as I can get, but you know, nevertheless, that doesn't mean that I can't create things like you see on the screen right there. The fact is that other people are artists and using their work and then getting paid for you using their work is going to be big business.

So, the technology is already there to do that. It's a matter of people getting involved and understanding the technology enough to actually create objects that we can use.

I want to take some application questions, so I can just get an idea kind of what people are interested in trying to use the technology for. I mean everybody decided to fill up the room for a reason, so what are some of the applications some of the people are thinking about doing with the technology?

Yes, sir?

M: Game development.

Jay Williams: Game development. That's an excellent one.

W: Industrial design.

Jay Williams: Industrial design; another one. We'll actually look at some hammers in a little bit.

M: Database interface.

Jay Williams: Database interface. We'll look at a sequel database interface in a second.

M: Training tutorials.

Jay Williams: Training tutorials for...?

M: [inaudible]

Jay Williams: Engine room, boiler representations, flow representation.

M: Virtual shopping mall.

Jay Williams: Virtual shopping mall, absolutely. Yes, ladies and gentlemen, step right up and get your objects.

M: [inaudible]

Jay Williams: That's what you're going to use those names for.

M: [inaudible]

Jay Williams: Right, it can actually do space analysis. In fact, space analysis is one of the projects that's going on for stacking ammunition, among other things. Things like that are actually going on out there as far as objects that people are doing things with.

Well, let's just take a second to look at the *WebSpace* program and then we'll come back to the author and we'll look at some of the authoring tools, because I want to use the *WebSpace* viewer to show you some of the functions that you have to think about when you are designing things.

There are multiple parts to the viewers and each of the viewers has a different... a little different way of implementing these particular things. Let's see which one we want to look at. Yeah, let's look at the castle.

The viewers themselves, basically, have several components. Obviously one of the components is just its own GUI interface where it has different parts and pieces, but even beyond that internally they have specific things that have to be built into these kind of browsers. These browsers are very different. There are basically, you know, three ways you can build a browser now and of the browsers that are available, they do different implementations, you know.

Anyway, the different kinds of browsers — there are the kind that are plug-ins and only plug-ins. In other words, will not run, stand-alone, require the browser itself to go retrieve the URL and hand it off to the actual in-line plug-in, okay. They are actually two subsets of those: one that displays the object directly in the browser, which is what *Web FX* from Paper Software

does and the plug-in from TGS will do as well; another which opens a separate window with a separate set of controls to view the actual object. You'll notice as I go back and forth from *WebSpace*, whenever I go to tell it to go to something else, I have to go back to *Netscape*, up to the "bookmarks" list and tell it to go retrieve it. That's because *WebSpace* is not a stand-alone browser. You actually have to use it in conjunction with the *Netscape* or the enhanced Mosaic browser to make it work properly.

WorldView works differently. WorldView is an independent browser. It can actually stand alone. Now, it doesn't show anything that *Netscape* does, however; it doesn't show text, it doesn't read HTML. It's reads VRML and VRML only. The advantage is you can form your own VRML list and you know, it runs on its own and there are some things it still has to do. It still has to know that you have a browser on your machine and those kind of things. Because it needs to know where to hand things off. Just like *Netscape* needs to know where it's helper application's are as it goes around.

Now, the third type of application doesn't exist except in alpha at the moment, and that's the be-all, end-all, Hi-I'm- everything application which incorporates both the browsing functions for HTML, VRML, for DBML for everything else under the sun.

How many people have heard of DBML?

M: [inaudible]

Jay Williams: Do you know what that is?

M: [inaudible]

Jay Williams: The first time I heard of it was at the Oracle presentation. If you looked at their slide, it was up on the wall. They went through this list: HTTP and HTML and they had DBML and nobody said a word about it. I am assuming that it's Database Modeling Language, but I haven't seen it yet, so I was just curious. I keep waiting for somebody to pop up and tell me what it is so I'll know. But I'm sure it's on the way and I'm sure there are several others. In fact, one of the papers that's in your thing, lists... because we've been having so many discussions and you can imagine the philosophy discussions that go on in Virtual Reality Modeling Language, you know, people come up and say, "Well, we really have to get the old factory smell involved in this."

And they're like, "Guys, look, we're not gonna get there...let's concentrate on, you know, what we've got going right now. We have enough problems as it is with audio."

And people come up with these series of acronyms of what they want to see and we'll go through a few of them just so you can hear them now, so you can say, "Well, I heard those first before they were officially adopted into the specification."

What you see in the browser are a lot of different things that are very important for 3-D space. Planes, okay, flat surfaces are absolutely critical, because they define things like floors, ceilings, et cetera. Clay Graham, one of the virtual architects — and we'll look at one of his sites — one of the first things that he developed that was interactive, was he has a room which is — and he's an employee of SGI — he has a room where the floor rises and falls along with SGI's stock, so he'd go visit the room. You can actually figure out how close you are to the floor or the ceiling. Obviously that's a use of planes to communicate a particular concept.

I'm going to show you another book that's very important. Computer guys are known to not read anything, but hard, technical manuals, but a few of us actually read other things. This book is called *Computer as Theater*, it's by Brenda Laurel. And now it features post-virtual

reality, as an extra chapter in the paperback edition. You no longer have to buy the hard, expensive \$70.00 hardback.

This book is an excellent...in fact, it is the best description of what it takes for us to visualize the things that we do in this world on a stage, which is basically what we're doing here. Okay, what we're doing is we're trying to create concepts both that exist in reality and that don't exist in reality and translate them to a stage. That's what the planes are for. The planes on this are designed so that we have a sense of space and place, okay.

The other thing that's absolutely critical is light. You'll see that there are some windows up on the side of this hallway here and you can see that the light is coming through those windows. That gives you a sense of direction. That gives you a sense of depth. That adds to the entire fact of being able to move and the fact that changes as we move, in terms of the light. Now, you will not see a change while I'm in motion, but when I stop, you'll see a change.

Now, there are two reasons for that: One, in interface design for anybody that's worked on that, you always know there are sacrifices to be made. Nothing can ever be as you would like it to be as far as design. Why? Because you're designing for multiple platforms. You can't tell necessarily the speed on the other end. You can't tell the necessary components, etc., etc. So, you have to design to the least common denominator in terms of being able to deliver.

One of the decisions was made in the creation of *WebSpace*, and there's been some consideration given in the actual specification, to the way the environment appears. There are two choices in terms of how you have your environment appear: Choice Number one is that when you're moving, you can have it all move to wire frame. All these objects that you see are made up of a collection of points. All polygons; all triangles are formed with lines to connecting points. So in any basic, 3-D model, the first thing you start out with is three points, okay. We'll get to there... there can be semantic arguments about how many points you're supposed to start with, but we'll say three. Because I don't think you can make a valid object with less than three points.

Basically, those three points are actually used to combine together to make everything else. Whenever you have a wire-frame drawing, and we'll see some examples... the floor, for example, is close to a wire-frame drawing... you basically see none of the shading; none of the texture; nothing except the points in the lines. That speeds up the drawing capability of the browser, so that you can quickly move from point to point. Okay, and we'll see some examples of that.

In this particular browser, they elected to go for maintaining the shading, slowing down the browser, but creating the effect that you're moving forward. What they decided not to do is the second thing that comes after the points and the wire frame, the textures. They fixed the textures and they don't change any of the textures. Every object that you create with three points... how many sides does it have? Two, right? Two sides is still a two-dimensional object. And you have two sides with three points, so, yeah, this is one of those chances where you could really break out that old high school trig book. It's sometimes useful in this. I get lost quite frequently in trying to figure out exactly the different places that we're going things.

But, you have two sides. And you can decide, in terms of your artistry, of coloring one or both sides. Either coloring them by flat objects or coloring them by textured objects. Okay, and we'll talk about the different file formats that you can use for textures and things like that.

How am I doing? Am I going to fast? Doing okay?

M: [inaudible]

Jay Williams: Good. All right. I have a tendency to go too fast, so if I start running off and leaving anybody, just stand up and yell. And if you have questions about what I'm talking about as I go,

stick your hand up and as soon as I get to a point to where I can answer it, I will or try to answer it.

So, what they decided to do was once the motion has stopped, they redraw the screen. They recast the lighting, which is actually a process of how the texture appears.

One of the most important things in creating your 3-D models after you've decided what the objects are going to be and where they're going to go in the frame, is to determine where the viewer's position is going to be. In other words, where the person who's seeing the object is going to approach the object from and then where the object is going to be lighted from. Okay, for example, you get a very different image if you have a back-lit object than if you have an light source behind the viewer's head. So cameras angles, the type of light cast by the camera; all of those things are very critical to how the scene is displayed.

So in all of the development tools and in all of the browsers, you'll see all different kinds of things to allow you to look at things from different perspectives.

One of the things in *WebSpace* is viewpoints. I suspect that viewpoints will be incorporated into the I.I of the spec; that is a speculation, it's not decided on for sure, but they're so handy for creating things like tours of an environment. So you, as the author of a site, can actually specify what you think the optimum viewpoints for your objects, for your actual worlds, are.

So what you're seeing down in this small tube at the bottom is all of the different sites that you can go to. By me clicking on this, it moves me to a particular section. Now, if your Italian is very good, you can actually read what these particular ones are, however since my Italian is nonexistent, I have to just guess.

Now, we come to this big, white space in the middle and everybody goes, "Oops, the screen's not redrawing."

Actually, the screen is redrawing. Most of the sites you're going to see are experimental sites. They're demo sites, either from a particular university; for a particular corporation; for somebody to do something. What you're actually seeing in the middle is the 3-D representation of white space, hanging in the middle of this castle. Because what you'll see is, as we move around this object... and we're going to translate ourselves to the side...and let's spend a minute and talk about controls, actually.

In this particular viewer, you have multiple controls. The joystick control controls basically motion in terms of forward, backwards, left, right. Okay, the small control on the side, right here, controls our up and down viewing; to look up; to look down; to get it centered again. It's not always easy.

This controls left/right translation and our levitational abilities, so that we can actually levitate ourselves above the scene or take ourselves down below the scene, okay. In this case, we'll move up a little bit. So you can have great sound effects, right? Yeah, we're working on audio, I'm telling you. That's what I do now. My friends come by when I'm working on all this stuff and they're like, "What are you doing, man?"

"I've got to provide the sound effects. They don't have any."

Seriously, though, we're going to move around the side of the object and the further I move away, the faster I'm going to move around the side of the object. And you're going to notice that what we have now is actually a 3-D object. Sometimes working this joystick is a real joy.

But what you can see is the actual 3-D outlines of the object to show you that there is something out in space.

The other things obviously would be that if you fly up to the window up there, this is known as the "fly control," and in fact in *WorldView* it's called "fly". *WorldView* uses the small picture on the right for all of its controls, rather than having the joystick control, so you actually

have... much like you have in the 3-D modeling program, you actually have a control pad viewpoint, rather than a joystick viewpoint. I sometimes get confused if I've got to pull back and turn to the left and the joystick, when I want to fly backwards, and you know. If I were a Nintendo controller, I'd be in good shape. Those are coming, by the way. The alternate input controller section is part of the I.I discussion at the moment. Whether or not everybody's going to agree on which plug we're going to plug into is the usual discussion.

"Use the joystick port."

"No, let's use the parallel port"

"No, use the zero port. I like the zero port better."

"Let's make a new port."

I mean, that's just... I stay out of that. Just tell me what you want to do with the hardware, guys.

Seriously though, as you can see, you can actually navigate around fairly well using these different things.

The other two objects that you see over here: One, this allows me to pick a particular point and say, "Hey, gosh, what's outside that window?"

And say, "Take me there now, you. Don't argue with me."

It won't let me fly up that high. It only let's me translate to things that are on my level. This is the old version. This the beta version that we're running here, I forgot. The actual released version will let you fly up from clicking on that, to go look at doors and those kinds of things.

The concept that allows us to do things like changing the lighting as we move and changing the objects and things that we move, is what's called "level of detail" or "LOD," for short. You see lots of LOD discussions going on.

LOD discussion involves what's going to happen when you reach a certain point. For example, as I'm standing back this far from a particular person, I can see that somebody has hair; they have a nose; they have eyes; they have all those kinds of things, but, until I get up really close, I can't tell what they're eyes look like or what their hair looks like. And because... when I'm this far away I don't need to know, right? Well, maybe I need to know, but if I need to know, I'll get closer. So the fact is that you're going to see lots of objects off in the distance. Also you have all kinds of issues with screen clutter, redraw capabilities, you know, all of those kinds of things. As you get away from an object, in fact if it's behind you, who cares if it's being redrawn, right? You can't see it. And so this also gets into some of the Euclidean discussions about whether or not we assume humans have four eyes, three eyes, two eyes or whether or not we're going to allow, you know, Sensaround sound.

If you look at the avatars in WorldChat, you'll actually see several aliens there. One of them has one eye. I'm like, "Hey, how come he has depth [inaudible]." I don't think they were happy when I pointed that out to them, but anyway. They have a fish. I'm like "What? Are you going to turn sideways to see everybody?"

So those kind of things obviously haven't come into play yet, but they will. I can guarantee it. Especially the game manufacturer's viewpoint. I guarantee you they're going to be critical. I mean, the ability to actually see all the games...I mean, this is hilarious. How many games are there out there that have aliens in them? Tons, right? They all see like humans. I'm like, "What's the use of that?"

If I want it to be an alien, I want it to be different. Anyway...

This gives us the ability to do that, using the level of detail things you can actually redefine, you know, the views that you can see, so you could actually limit those things. It hasn't been done yet. You're going to hear me talk, by the way, about a lot of things that haven't been

done yet. I only have five fingers on each hand; yeah, I'm human. Five fingers on each hand; four fingers and a thumb. But you know, typing and putting the things into place is very hard.

Are there questions on the capabilities of the browsers in terms of VRML? In terms of what they can display.

I could go into great detail about cameras and level of detail and all those things, but it's very complex, if you don't have at least some of the 3-D background. There's a fairly decent primer in the book right there. There are very, very good books out there on all kinds of 3-D modeling. If you haven't ever played with a 3-D modeling program and you're even vaguely thinking about doing this, you're going to have to sit down and do one of two things: find your friend who's the great 3-D modeler and you've got the concepts or sit down and do some of the modeling yourself. You should probably do Number Two, whether you're going to go get someone else to help you do the actual graphics design or not.

Yes, sir?

M: Do most of the browsers [inaudible]

Jay Williams: Yes, well let me address the Windows '95 problem with browsers.

Most of the browsers and all the pieces were originally developed in UNIX systems. GZIP, of course, is a standard feature of most of the UNIX systems. It's also a multi-threaded environment, so that it knows how to walk and chew gum at the same time.

Windows '95 is working on walking and working on finding some gum. And so as it gets closer to that stage where it can actually do both at the same time, you get around that problem. There's a way to make it work. You have to mess with some of the files, so that Windows knows particularly where GZIP is all the time, and then you know, your actual browsers there and it doesn't slow down the Windows' translation process a little bit to do it.

In fact, I spoke with some of the guys that are here that built two different compression packages and I explained to them the desperate need of one of their packages to do that and I suspect that if they can make the code change to it that we'll see, fairly soon, a couple of packages that will do it on the fly. WINZIP will almost do it on the fly, so we're getting very close to where they can do that.

The GZIP question is a very good one.

One of the things that we've done to make sure that the files actually come across the Net at some speed, and you'll see why when we go to one of the Palladium sites. When I go to the Paladium, one of the Lightscape sites — when you see some of the file sizes, GZIP the files. That allows us, since they are text, to get very, very good compression on the files to bring them across the net.

The work on the UNIX machine is when they bring them across the Net, it copies into a temp directory, a temporary directory where they're automatically unstuffed and accessible to the local machine.

Windows, of course, attempts to do that and it brings them over, but it doesn't have any true caching. And if you recall when Netscape originally started to do things or when, actually, Mosaic was doing things, you had to physically download the file to view it. Now, I know that's the Stone Age for a lot of people. There's probably people here that don't even remember that anymore, but you had to actually bring the file and the graphics down to your local machine to see them. That's still the case now. Cache and removal and clean up is one of the things that's probably not going to be in 1.1; we'll probably have to wait for 2.0, because of a lot of technical issues again with the file system kind of things to make sure that it cleans up after itself, so that after you're through viewing some of these virtual worlds, it gets rid of the files.

So, if you're using this on a Windows machine, particularly you have to watch your temp directory very closely, because it will fill up very, very, very fast as you're driving through all these different worlds. That's a good-news, bad-news situation. That's the bad news. The good news is: You have all the models for you to view. They don't go away, so if you want to go back and open up another model, you can. It's no problem.

We're going to move to a different model.

On the Mac side of the fence you have to download the models. There's no caching. Let's talk about the Mac for just a second.

The Macintosh has been approaching the 3-D environment for a long time. It has some of the best rendering tools. It has some of the best graphic capabilities of anyone that's participating in the industry. They have Macintosh...or Apple has two strategies that they're pursuing that are somewhat confusing and Mike explained a little bit about them and I'll explain a little bit in more detail.

QuickTime VR is a photographic reproduction or animated reproduction space. That's its job. Its job is to take either existing photographs — you can get your professional photographer with a 105mm lens and some very precise gear and send him out to photograph an environment and you can use various tools that are available for QuickTime VR and recreate that environment in 3-D. It's not really 3-D; it's pseudo-3-D. It's 2-D, you know, without the glasses, so to speak.

There are tools, by the way, where you can create 3-D worlds where you have to use the glasses, too. That's why somebody came in yesterday and says, "Hey, this isn't 3-D. It's still 2-D"

I go, "I got some glasses here."

Anyway, the second thing that they have going on is QuickTime 3-D, okay? To my mind, 3-D is the more interesting of the two technologies. I mean QuickTime VR is very nice and you can see The Enterprise and walk around the bridge, punch buttons and all that, but in QuickTime 3-D you can actually take objects and give them properties.

Now, their format is known as 3-D MF, 3-D Model Format, and it creates all kinds of objects and does all kinds of things. The current viewer that's available for that, other than their simple viewer, is one that's called *Whirlwind*, which is now in 1.0 Delta 5 is the version number of the product and it's been making really good strides. It can read some VRML files.

Now, you say, "Gee Jay, there's a specification out there; what do you mean it can read some VRML files?"

Well, yes there's a specification; however, remember I mentioned earlier that different programs output different kinds of files into the VRML format. The father of all of these things was the *Inventor* language with Open GL. The ones it can't read are the ones that were created with the *Inventor* export feature for VRML, which constitutes about 75% of the models that are available at the moment, because as you can see, this is the premiere platform that's able to do those kinds of things.

So on the Mac side of this, this bug or feature is evident by seeing a blank screen when you download a model, so if you try to go to Silicon Surf and get on Silicon Surf in 3-D mode, you will find it doesn't work. That's because all of those were generated with *Open Inventor*.

Now, he is working overtime to try and fix that particular issue. I think there's more than one person, but it's a very small company. And so I suspect that we'll see that very soon, I hope.

I also know that Apple is trying to come out with a viewer as well.

Yes, sir?

M: [inaudible]

Jay Williams: They are coming down the pike. Most of the ray-tracing companies have been so busy working on the complexities of the ray-tracing thing that now they're saying, "Gee polygons. I guess we can do that."

And so they're getting very close to where they're actually going to have some tools. I personally am not an expert on the ray-tracing field or the applications, but rumor has it on the list that some of the people are working on it; I don't know who in particular, though.

M: [inaudible]

Jay Williams: Oh, it's being talked about. I've seen it blow a couple of times. By the way, the VRML list is housed, wired and it's extremely active and it's pretty technical, so take the digest version. Let me just say that right off the bat, because it's fairly active and two, be prepared to see a bunch of stuff that looks like gibberish, you know, unless you happen to have a lot of 3-D tracing background and things.

M: [inaudible]

Jay Williams: Absolutely.

M: [inaudible]

Jay Williams: You probably won't because you'll have a code error, probably before that happens, because it would be very hard if your triangle's intersect — you say in the Origami, those are intersections of triangles and we were folding the papers right.

M: Every time I fold papers, it doesn't intersect itself.

Jay Williams: Right, and that's the same thing that occurs as VRML. You can't code it so that you're going to intersect triangles, so you're going to get a coding error, right.

M: I can't have two different objects?

Jay Williams: You can have two different objects, but they're going to merge together in a single object on the screen because you're not going to define any separators in between them, right? Unless you're going to define outline.

I mean, what you're going to do is you're going to get an overlay. It's a 2-D environment, okay. You have two triangles — you saw the sphere intersecting the pyramid?

M: No, I didn't.

Jay Williams: Okay, if we go back and you see the...

M: [inaudible]

Jay Williams: No, that's fine. It's no problem. I never mind going back. I may kill myself, but I don't mind going back.

M: [inaudible]

Jay Williams: Yeah, don't worry, I'll get there first. Let's fly down to the pyramid here. Whoa, under the pyramid! And if we go, actually, to the door — Oh, I forgot, he didn't specify views on this one. This is where the author didn't specify any views and you can see how much easier it makes traveling to the world when the author says, "I'm going to take you to the door," rather than not giving you any hint where the door is other than saying, "It's over by that pyramid somewhere."

And obviously the further you move the actual drawing, the joystick or the cursor up in front of the joystick, the faster you go and it does take some getting used to. And it's different from machine to machine.

And if you ever came to this model and you didn't know that little speck was the door, it could take you a while to find it.

But as we get closer up to the door, you'll see that that's a sphere intersecting the side of the pyramid. Actually you'll see it turn into a cone in a couple of sections, because he's experimenting with level of detail, but didn't get it quite right. Let's go inside. Overtranslation... stop that...browser out of control... okay, we're making great progress. You can actually see it now intersecting the side, so I mean you can have two triangles intersecting. You can have to pyramids intersecting. You can have anything that you can...

M: [inaudible]

Jay Williams: Correct, right.

M: [inaudible]

Jay Williams: That's handled by the engine, the rendering engine. Each browser has a rendering engine built into it. This is another difference between the browsers. Different browsers use different rendering technologies. Microsoft has acquired its own rendering technology by buying up another company, as usual, and — yeah, I'm sure I shocked everybody here — but it's a very good rendering technology and so the rendering technology for 3-D is actually built into Windows '95, so I would say you're going to be able to see the products of that very soon and VRML is probably going to be part of some of the stuff that they're going to be doing.

There are people from Microsoft on the development team for I.I., the specification.

Let's go look at a couple of sites and where to go get things: First place to start, if you're going to go look at things, is actually at vrml.wire.com.

This forum actually has all different kinds of things on it and is updated on a strange basis, but you can actually go find things. If you want to find out about the history, you can go read the whole Hypermail archive and listen to everybody's arguments over and over and over. If you want to find out about what's going on in the future, you can go to the VRML Future's Forum. And we'll go there in a little bit and look at some of the things that are under discussion. If you want to go find out what's being done and what's been done, out and about, you can go to the VRML Repository at San Diego Super Computer Center, which is one of their repositories; there are several place that are connected there. You can also see the notes from SIGGRAPH, which is very popular this year and has a lot of people discussing all different kinds of things.

Actually, Mark Pesce's going to be at Internet and E-Mail World, I think, which is coming up in a few weeks, again here in Boston. And also there's actually going to be a VRML World next spring. I don't have the specs on it yet, but it's coming from your friends at Mecklermedia.

The History of Theory section: This paper on Cyberspace defines a lot of the challenges that are out there for making things work. VRML is one part of Cyberspace. We all know there's a lot of other parts. Mark, Tony and Peter go through and define a lot more things in this paper. It's included in the handouts that we're going to give you. In fact, it's the first page in the handouts that we're going to give you.

Just so you make sure you have enough stuff on the plane and at the hotel, we've got a pretty thick package here. Everything that's in here is available on-line, so if you don't feel like carrying it around, that's great. You may have to drive around a little bit to find it. Actually Monday my home page is going to have part of this presentation up on it, so you'll be able to go to Serve.Net and check out different things. It's on my card. If you didn't get a card, I've got them up here. I can get you one.

So if you don't feel like carrying this stuff around, you don't have to. It's a very good paper. You can also join the mailing list from here as well.

We'll go to the Repository. Here's a whole discussion about everything and job posting and all that funny stuff. We'll go to example applications, because that's a really interesting part.

Just to get an idea of the kinds of things that are going on, I'm just going to scroll through the list real fast, because it's pretty long. I mean, there's a ton of stuff going on and this list grows every week. It's a big list. I won't even go through the whole thing. But it suffices to say that there are lots and lots of things.

For example, how many people have seen Feathers McGraw?
Ever seen that?

Well, we've got to see Feathers McGraw who's a penguin in disguise as the chick and, I'm sorry, we just have to go look at that one, because I feel strongly that it's important for people to see that.

We can't get from this Net — go look at this at home when you get a chance. Make sure that nobody's around to see you looking at it, but go ahead.

By the way, one thing I want you to know if we look at this OZ-VRML section, we want you to notice that among the projects undertaken is a shader technology from Microsoft Corp. and Soft Image, so you're beginning to see some of the larger corporations working on different things. I think we can get to Oz. Can we get to Oz? I hope so.

Are there questions? On browsers? Interaction with the other things?

What you can do...

Yes.

M: [inaudible]

Jay Williams: Yeah, I'm going to actually go through *Web Author*. I'm actually going to drive through *Web Author* and show you how to make a couple of model and how to fly around on a couple of things.

Ah, nice slow link.

M: [inaudible]

Jay Williams: Remember I mentioned that people are creating objects. You could actually go through the sections. You can see the interactive camera sections. You can see a mike section — lot's of different pieces that are being developed, so I'm obviously not going to drive through every one, because obviously we wouldn't get anything else done if we did. You can spend an extremely long period of time doing these.

I'm going to skip down to some of the entertainment things, assuming I have one in here...there's some really great physics stuff. Anybody that's into physics, there's some really neat things in here. You can actually go look at the Klingon Battle Cruiser.

[Tape change]

M: [inaudible]

Jay Williams: Yeah, that's Number Two. No, it's not quite that, but you'll notice where it was made. Your tax dollars at work.

M: [inaudible]

Jay Williams: Oh, absolutely, he's keeping it on his own server, too. We're not paying for that link at all, trust me. There's an X-Wing Fighter there too, but we'll skip that one for the moment.

Seriously, though, the list of objects that you can actually go into...these are all different things. I mean, you'll see that there's Meshmart...people that are creating whole different kinds of things. You can see all kinds of people that are working on musical things.

Let's go to the Virtual Lounge. How many people have been to IUMA, Internet Underground Music Archive? Okay, great. Let's go to the Virtual Lounge. Now, you'll notice that one of the features that's going on here is objects are being loaded as it can get them, okay. So, different parts will appear. Now, there are different ways you can do this. You can define this to say, "Hey, show me a wire-frame box," defining the space of the object before it comes in. So, if you're driving around the space, you won't walk through and a brick falls on top of you, right, and things like that. Or you can just have them appear as IUMA.

M: [inaudible]

Jay Williams: Say again? I'm sorry.

M: [inaudible]

Jay Williams: That's something that you can set, depending on the browser. It's set, actually, in the spec. You define it in the spec, but you can actually turn it on and off with some of the browsers. So, as an author, you can define it how you want to do it and then as a viewer, the viewer can sometimes decide to override the author. There are all different kinds of things going on here. We'll click on a couple of them.

Candy bar, anybody?

Now, notice this is taking us directly to hypertext, okay? All right? So, you can actually go get direct hypertext from the VR links. This is an example of how interactivity works now on VRML. You basically create a site, the couch, for instance. We can see it pretty close. How close would you like to see the couch? Anyway, you get the picture. Nice couch, nice table. You can actually listen to music in the speaker room. They've changed the dynamics. You notice this blocked space out here? It simply means there's nothing there. Again, they've basically not defined any more views for the particular things. We can actually go look at the stereo, all right?

Look at what highlights. You'll notice the Play actually works. It brings up a particular different song. It clicks up a random song every time you click on it so you can hear the

different ones — 6.8 meg. It'll take a while, but on this link it's been taking a while. Well, you keep working on that and we'll go drive around in *Web Author*.

Okay. We'll talk about one product, *Web Author*. Brand new. This is probably the most powerful VRML editor available. It has so many features that I can't tell you about all of them. I've spent several hours working with it and I keep finding new and nifty things. That's pretty fast. Okay, that's enough of that. It's a very exciting tune for me. You know, you get random music from there.

M: [inaudible]

Jay Williams: You're looking at it. The Sun platform is eminently ready, the NT platform is following — or the Windows '95 NT platform is following eminently after that; I suspect January. Currently, what's running — I can give you a quick rundown of what's running on what platforms. *Virtus Walk-Through Pros* is available on Windows, Windows for Work Groups, Windows '95 and Windows NT and the Macintosh —

M: [inaudible]

Jay Williams: That's *Virtus Pro*. That's *Virtus Walk-Through Pro*. Yeah, V-i-r-t-u-s. And they have down-loadable demos at www.virtus.com. — *Home Builder*, which basically builds space, is available for the Windows platform. It's included on there. I don't know their direct URL off the top of my head. It's a fairly limited product. You can only make walls and floors and windows and things like that, so there's no comparison — of the rendering programs, the *Virtus* program is the one that's available on multiple platforms and it's the one I use to do stuff. It's got a good template, good libraries, very good tutorial that comes with it. It has very good support. It's an old program. It's been around a long time, which means it works. Not that *WebSpace Author* doesn't. *WebSpace Author* does. I have not crashed this program, and I've got to tell you, with Version 1.0, that's pretty amazing. I attribute some of that to the fact that it's running on IRX.

So, there are lot of things you would expect to have in a graphics program that you can do. You can actually go through and select all objects and select different kinds of things. One of the concepts in 3-D rendering is a parent-child relationship which, if you've done a lot of things, you might be familiar with. It allows you to link objects and hierarchies of objects and groups of objects together by defining which objects relate to others and what the relationship is between those. You'll notice in the view spec that you can actually go down and do all different kinds of things. You can show links. For instance, if there are linking objects, they'll actually show up. You'll watch as I go over a particular one here, if I can find one. I know there's one here. You should be able to see it. Well, I'll find one in a minute.

You can actually show the level of detail, show in-lines, the cull volumes — let's talk about culling for just a second. Culling has to do — and there are a lot of terms here, so we have most of them in a glossary section, and various text cover a lot of them, but I'll try and define them as we go. Culling is that process of when I say, if you walk by something and it's suddenly behind you and you no longer need the object in your scene — by the way, these are called scenes, as they're putting them together — then it culls the object out of the memory, so it doesn't have to redraw it; it doesn't have to keep track of it; it doesn't have to know what's going on with it. So, with cull volumes you can set how fast to get rid of those objects in a particular thing.

Show triangle count. Let me talk about why that's important. The triangle count is going to define the size of your model, okay? Currently, a Pentium 90 with 16 megs of RAM running Windows '95 or a PowerMac 8100, 16 megs of RAM, etceteras, can reasonably display 10,000

triangles before it blows up, okay? When I say blow up, I mean CPU goes down to where it can't process any more depth, so 10,000 is the ceiling, absolute ceiling. Not middle-of-the-road ceiling, maximum ceiling. That just has to do with CPU processor time, etceteras, etceteras, etceteras. It's a technological thing. Obviously, that number's going to get bigger as processors get faster, more powerful. It's not really a function of disk space, it's not really a function of RAM, other than the physical ability to load the file in there. It all has to do with processor, in this case, because this is the mathematical function that it has to do. Obviously, the Indy and other types of machines like that can process more triangles than that. That's why they're ones that are used for 3-D rendering and authoring, so they're quite commonly used for all those things.

M: [inaudible]

Jay Williams: Say again.

M: [inaudible]

Jay Williams: There are 3,130, okay? That's why that feature's there. This is a great feature. No other development program can go count triangles that fast, I'm telling you. If you're going to be doing some serious development on this and you've got to start tomorrow, here's the solution right here. Go over to the SGI booth and fill out an order form. I'm serious, because there's literally nothing else that's as powerful with as much support. I mean, they actually have five people that can answer your questions on VRML, okay. Anybody else that's out there that has text support departments is much smaller. TGS has a very good thing for their products, but they're still rolling out into beta and into production, and their authoring tools are still at least a quarter away.

Appearances — we can go through and click on different things. There are all different kinds of pallets that are used to determine color and form of objects. In the VRML specification, you have a lot of different things you can deal with. Material is what you would expect it to be, the substance of the design, and this let's you very quickly look at the pallet and cruise through and see what your different objects and things are, and you can look at all different kinds of sections. Obviously, we can say we're looking at the glass. Well, actually, I'm looking at some tropical stuff I want to see. Obviously, it's going to alter the nature of the patterns that you can use.

This is a material editor. This let's you create all those materials that you were seeing in the other ones. So you can actually go in and say, "Yeah, you know, this Fall I really need one that looks a little different," right, and actually directly alters each of the different sections. You can go to as much detailing creation of these pallets as you would like to go. This is the advantage of SGI already having all of this rendering technology and having all of these things to build it in their browser. What they've done is taken kind of a best-of-the-best from their other tools that are available and incorporated it into their authoring program. And, I mean, I've yet to come up with something — and, again, I'm not a 3-D modeler — but other things on here I could never imagine doing. Going in and editing the color map? Not me, buddy. Get somebody else. I'll take your color. I like your color very much, thank you. Anyway, you can get the editor and, obviously, we now have a whole new sheen to our world. And you're going to see me destroy this world, as we move through it, by the way. This is the part Mike warned you about when he said, give them a break on the artistic side. We'll have a polka dot house here in a minute, if I keep this up.

This is a texture editor. Textures are things that are applied to your planes that are created with a-polygons. So, you can go through and say, "Love that, mm-mm," and you can simply say, "that's really a good one." Let's see if I can do this here...yeah, that's it, three components...wonderful...let me find this — there's another one that's really good in here. It even looks more ugly. Let's do this one, the Talouse Latrec version...so you can see, we've now given the Talouse Latrec look to our new world by re-texturing the walls. Obviously, you can have a lot of fun. I mean, I can sit here for hours and just cruise around. "Wow, look at this. Hey, buddy, look at this one. This one's great." The best is when you actually have a digitizing camera hooked up. You can take a picture of yourself and then you can have the ultimate ego image on the walls, as you become the texture of your place.

M: [inaudible]

Jay Williams: Oh, yes. You can go down and select different parts. And I'll booster the selection. I'm in the unconstrained view, which does everything. You can actually go through a front construction view, which puts everything and lines it up directly — angled views, left construction view, which looks at it from the other side. Top construction view, which looks down upon the thing, all right, so you can actually see how the layout actually works and you can actually see orthogonal, if you want to, as well.

Yes, sir.

M: [inaudible]

Jay Williams: Right, yes. The only thing that this does, above and beyond *Strata*, is — I can't even phrase it in terms of above and beyond. What it does is it's for people who aren't used to the 3-D rendering environment. It basically removes all those things from *Strata*. You can go into as much detail as *Strata* has, but, as you know, when you walk up to *Strata* and sit down, you better have a damn good idea of exactly what pieces you want to do and model, because it's very, very powerful. I mean, it takes a long time to learn how to drive *Strata*. You can sit down and click this and build images — and you'll see me build a few now.

M: [inaudible]

Jay Williams: Yes, it's more entry level, but let's call it more tailored for this purpose. *Strata*, of course, is purposeful for almost everything. This is limited in purpose, in that it generates VRML files, okay? I mean, you're not going to generate, you know, your standard *Strata* files out of this. The texture editing here is no way as powerful as *Strata*'s texture or Renderman's texture editor. So, if you're really planning on creating some serious new dimensional textures, you need to get some serious rendering, modeling program. If you're planning on using existing constructs or taking texture maps, loading them into here to use, you're looking at an authoring workbench environment, that's what this is.

M: [inaudible]

Jay Williams: We're going to go through shapes in a minute. I'm just kind of driving through the buttons, as they go across the screen. We're going to look at the objects editor in just a second, assuming I don't kill myself.

Okay. Where was I? Level of detail editor. I just wanted to show you this so you could get an idea as far as the level of detail. Notice that it triangle counts 418 in the next level of

detail. There's only three levels of detail in here — actually, there's only three — yeah, there should be another one — yeah — zero — actually. Level of detail starts at zero — hmm, I don't know if that's a bug or not...can I see the transitions from here? — not really, no. For some reason, I can't see them from here. That's because it probably doesn't have any level of detail specified for this environment — oh, I'm in top construction view. That's why. I'll go back to my unconstrained view here. Yeah, we basically don't have any levels of detail specified for this one. Again, levels of detail would be if we were defining which sections — you can go into each section and specify how many triangles we're going to show at what level of detail and what's going to be attached to that level of detail, in terms of motion.

You can see you have lots of fun and exciting editors over here. There's the Talouse Lautrec section. You can actually see that we can use the pointer tool which will change our scene size — you can actually drive around and do all kinds of fun things with this one. I'm going to slow down the SGI. Watch me. Let me change my view again. Now, obviously, what we did was we increased the size of the scene and we moved back further so you can actually see what your different pieces are. The dolly moves us in and out, right? You can see the points defining the size of the scene. Usually, when you start a scene, you lay out your original points and decide how big you want the scene to be before you place the objects, which gives you a framework. This is obviously your rotational, all right? A-h-h! They'll all fall off if you turn it upside down and shake really hard. No, that won't happen. I promise. This is too much fun. I mean, the bad news is my friends come in and see me doing this and they're like, "What are you doing? Get a job. What are you doing, man? Put that away."

These are all your different tools. Let's look at particular things. Let's say we want to set a link for a particular object. All you simply do — and this is where it really gets different from *Strata* and things like that — you won't find a link or URL function in there. Basically go through and define where you're going to go to and what you're going to link it to and whether you're linking it to a viewpoint. If you want to form those viewpoints when you move around a particular object, you can simply go in here and tell it where it's going to go or what type of link it's going to be. Obviously, if you have a whole bunch you've already done — they all appear in the menu here — it's very, very simple to connect it to a particular item. If you want to make an in-line file — that's a call to another object — this is where you do that object. It defines a sphere. It'll define the object size, so if you know you're going to get a sofa image from somewhere else, it'll show you an actual picture in here. I don't have any ready to do, so I can't show you that particular one. This, again, creates the viewpoint. You can position a camera — say we want to be over there for this particular viewpoint, and we could give it a name. Then as you go through and work through your different viewpoints, you can set links. No, I'd have to put the viewpoint in the URL, if I did it that way. You can move through the viewpoints and do different kinds of things.

Let's look at Text Modeler first. Somebody asked earlier about text. My biggest thing that I've been doing is saying, we've got to have some text in here. I want to go pick up a book and open it and see the text. Currently, when you do that, basically, the best way to do it to flip back to an actual Web page to display the text. One of my first job on applets is a page-turning, Java applet. It actually just has a book where the pages turn. Everybody says I'm archaic, but I think it's kind of fun, you know, the pages turn, etceteras. So, I'm going to have a link to some books for one of the applications we're doing that goes back to that book and actually flips the pages. So, right now, I currently have to go display that either in a Java window or in a Netscape window. But, for example, if we're working on text, like we are here, we can do whatever we like to do with the text. We can decide that we want to extrude things. We could shift the way we want to do the spacing on the text. We could say oh, yes, we're going to use solid text so give me some really fun stuff to play with so I can change the extrusion profile on the text. I can

say, oh, that font family, how ugly; I need Palatino; I really hate that; and we need some italicized text, and I actually need to rotate it a little bit. Copy...quit. And then, of course, we can come up here and do the infamous edit-paste. It's going to ask me where I want it, and we can paste the text in.

Shape Modeler? This is where you get into some really fun and exciting things, where I can really do some damage. Basically you come in and define different sections of your shapes. Let's try this one. It makes some really exciting shapes like this. Not that they make any sense, but they're really fun shapes. And obviously, you have your moving in and out capabilities, rotational capabilities. You can look at all sizes and shapes. You get the idea of the power of this just by what we're doing here. I mean, that's a shape that has never existed in anybody's mind but my own, trust me; nor will it ever probably exist in reality, nor should it ever exist in reality. Obviously, you can spline everything; you can do some pretty wild stuff when you start turning on the spline. I slowed it down a little bit. There we go. I wanted to see if we could see the actual splining effect. Come on up there. Obviously, so we can make the infamous mushroom. Splines are obviously what are required to make lots of different things, so that we invert everything, so that when we turn it over now, we see the reverse of the spline, right? And you can do all kinds of degradation to change the way it looks. You can go in and say, oh, actually, gosh, I really meant to connect this into a full polygon here. So, obviously, you can see we're altering the nature of the spline every time we do that. Turn sides off, you know; change it back and forth. Multiple objects that you can do this with.

Are there questions on this, other than, gee, Jay, can't you make this more interesting?

M: [inaudible]

Jay Williams: No. Obviously, you can go through and change and add new objects and move objects around; all of those kinds of things. Your Save As function, obviously, you see you're going to save all these in its own particular modeling format. It's read by WebSpace Author.

M: [inaudible]

Jay Williams: Which technique?

M: [inaudible]

Jay Williams: Rendering. That's called rendering. Any type of thing that you're doing where you're actually trying to take an object and model it in a particular 3-D space is usually referred to as rendering.

M: [inaudible]

Jay Williams: I'm not familiar with that. We could probably ask one of the 3-D modelers. I know we have at least one in here, right? Somebody that's worked with 3-D stuff? Is there a subtopic underneath rendering where you do splining. I think it's all just lumped under rendering, right?

M: [inaudible]

Jay Williams: We can bring our images into the particular thing. One of the things that's important about this program that, again, *Strata* doesn't have, is a polygon reduction editor. What that does is — no, it doesn't delete your polygons. What it does is figures out the most

efficient use of your polygons. So, if like me, you're a dunce and create those kinds of images like the one I just did, it doesn't really explain or use polygons in an efficient manner. This will actually go through and try and conserve surface edges and merge coordinates and get rid of the extra polygons and reduce your polygon count to make your model run faster, okay? This is a great tool, because if you can imagine what it would take for me to go in and go, "Gee, Jay, I wonder if there's more polygons than I need in that particular object?" I'd be there a long time figuring that out. And, you'll notice it has Help and says, "In-lines made with Make Tool may be unmade if you edited the unpublish load space alter file." It does give you a nice warning to let you know you can destroy everything you just did very quickly.

Again, here's the new viewpoint we created. We can move around to it. It's not very exciting. Actually, that's where we were at. There's an entry, so you can look at these from the viewpoint that you've already created. There's the entry from stairs, right. Back to B, which we didn't define very well. Make. We pretty much went through all of these, right?

Outline Viewer. Did we look at that one? Outline Viewer tell us what all we've got going on in here. This is actually an outline view of the VRML file, okay? So, it's telling us what different sections we have in there. So, you can look at separators, bindings, different pieces of the file. This is to give you an idea of the breakdown, just like if you were looking at HTML outline, you'd see HTML, section, link, page, you know, all different things. These are actually the separators and the different sections for each of the images that are in there.

M: [inaudible]

Jay Williams: Yes.

M: [inaudible]

Jay Williams: Conversion, yeah. There are conversion routines for almost all of the different things out there.

What we did now was basically move into preview mode. You'll notice that it automatically launched *WebSpace Navigator* and put us in examiner view mode so we can actually go see what our model is going to drive like. So, at this point, I can say, view-walk-viewer. Now I've got a ton of textures and everything. I've been totaling messing with this particular image, so you're going to see a lot of entertaining parts to it, and it's going to take a while to redraw, mostly because of the texture mapping I did. I used extremely intensive texture map on this.

Let's talk about texture mapping for a minute. Currently, there is no graphic specification in *VRML 1.0* for texture mapping. In other words, they don't say you have to use Type X to do that. This program uses RGB files for its texture map files, because that is an accepted standard on the SGI platform and *Open Inventor* and all the other tool sets. There is a file format defined as SF Image, which is a special file format that you can use. Most people are using JPEGs and GIF format for their texture files and image file formats. The problem with that is that the files have to have been resident in the WRL directory, as the program actually calls them for texture map. Inclusion of those things in the actual formats is going to be part of I.I., to solve that dilemma.

Yes.

M: [inaudible]

Jay Williams: You can actually define anything to point to the file. The question is whether or not the viewer is going to support it. You see, there are multiple different viewers, and so I don't think any other viewers support in that format at the moment. So far, the supported formats that I know of are RGB, JPEG, GIF and the SF Image format, which is an extremely strange image format that most things don't use. So, this viewer, for example, supports RGB in this version. So, if you're using texture and image maps and you want *WebSpace* viewers to be able to see them, they need to be in RGB format.

JPEG's and GIF's are not supported by this viewer now; however, the *WorldView* supports JPEG's and GIF's. So, how much you use textures and how you do it, that's why you'll see a lot of things that are non-textured. Also, textures add a lot of overhead to the images, especially as you saw redrawing these particular sections of things.

M: [inaudible]

Jay Williams: Yes.

M: [inaudible]

Jay Williams: There are couple on the CD-ROM that's in Pesce's book — the DOS conversion tool is in there that converts from AutoCAD, *Strata*, I think, and something else. I can't remember what else it converts from. *Calgary True Space* now has a built-in VRML export function, as well, so if you're using Calgary's product — it's a very good product, it's available on there. It's very, very powerful.

M: [inaudible]

Jay Williams: The conversion routine, you pretty much have to use a DOS conversion program, at the moment. I don't think there's a Mac conversion program. There's not one that I know of. I'm trying to think if a *Virtus* will import *Strata*. I think it will. I'm not positive. I think it'll import a *Strata* object and then you could export it to VRML out of its export function.

M: [inaudible]

Jay Williams: It has to, okay? Now, I asked somebody this — I asked exactly the same question a couple of days ago and the answer was, "Uh, I'll get back to you on that." So, if it's not in the release-X right this moment, it'll for sure be in the next release.

M: [inaudible]

Jay Williams: Not the scaled-down ones. The real *Calgary True Space* program, though, you can do — I mean, I have graphics friends that swear by it, so, I mean, I feel comfortable in their saying it's a great product, yes.

Jay Williams: If anybody else does need to leave, just yell. I'll give you the materials and you can take off.

M: [inaudible]

Jay Williams: SGI. It's on the SGI. This is running on the Indy.

M: [inaudible]

Jay Williams: TGS is doing the ports to every other platform, except the Indy. They have the rights to do things. For example, the *WebSpace Viewer* is available right this second on the TGS site for the Windows platform.

The *Navigator*, correct. The authoring platform probably won't be available till first quarter on anything other than the SGI platform, for this authoring tool. Now, there are, like I said, other authoring tools that you can use. For example, for the Mac and the PC, you can use the *Virtus Walk-Through*, VRML version or the *Pro* version, either one. *Pro* version supports the export, as well.

M: [inaudible]

Jay Williams: This is the most-powerful one to date. If you have to deliver things that are going to be the highest-quality possible with the best overall integrated development environment that you know the most of the viewer — I mean, the number one viewer is *WebSpace*, so if you want the most that people are going to be able to see — and also, what's going to happen is this is going to be updated, you know, hourly. The good news of having the SGI development team and the *Open Inventor* team contributing parts of this product is that if there are going to be new features appearing — not that other companies aren't going to be — *Web FX* and *Paper Software* are committed to making some newer features appear, as well. They don't quite have the horsepower in this marketplace as SGI does, however.

M: [inaudible]

Jay Williams: Oh, it can view them. It views the *Virtus* —

M: [inaudible]

Jay Williams: It works fine. If you use *Virtus* on the Mac to create objects — at least it has for all the objects I've created so far. You know, again, it's one of those things that it's brand spanking new, so, you know, we're talking a month and a half of development here, so...

M: [inaudible]

Jay Williams: That's what I've been doing now. In fact, I use *Virtus* on my PowerBook sitting over there that actually runs on a 520. Don't get in a hurry creating any polygonal objects on the 520, but the Power PC Card's on the way any day now, I promise.

M: [inaudible]

Jay Williams: The plug-in is going to be available from TGS. I have the beta now. It'll be in release in mere weeks.

M: [inaudible]

Jay Williams: Yeah. And it's available for 1.1 — you can run it now in *Netscape 1.12* and the *Web FX* add-in. They released their 2.0 add-in, but it has a bug, and so they took it back. And so it'll be out really, really soon again. I'm sure it's a minor thing to fix.

M: [inaudible]

Jay Williams: Sure, absolutely. I'm sorry. My tether is not very long here. Sure. Gotta go, too? Questions. I'm answering questions while I'm handing these wonderful things out.

M: [inaudible]

Jay Williams: Let's talk about it. Well, myself, it would take a lot. But, most people would probably get a lot faster. But, one of the projects that's in Mark Pesce's book is called Project 188, I think, was the final name. Project 188, which is an actual attempt to model an actual environment. There's a house — in fact, it's not very far away over here — which actually became an art house through the coincidence of having a floor and furniture shop around the corner that donated a bunch of their cast-off materials: old carpet, old stuff and everything, and they just put it on every wall, every surface available. There's black satin on one roof and there's, you know, fuzzy carpet down one wall and all these different kinds of things. In fact, if somebody's got that text there, will you look up the URL for Project 188. We can actually look at the room and go see it. And what they did was they went through — and it also has all kinds of Art Deco objects and weird objects that friends brought over and they said, oh, this looks perfect in your house. You know, like don't bring it to me.

Anyway, so they went through and they decided there were 150 objects that they'd try and model to recreate the rooms of the house. And so they went through the process, but they agreed when they did it that they were going to digitize as little as possible to save time, energy and everything else. It took a couple of months, part time, to put the project together. We'll look at what the outcome of it is. You can follow the stage-by-stage process in the text. It'll actually go piece by piece by piece, explaining how they decided to do it, what the problems they encountered were, you know, what they had to give up to get this and what they had to do to do X, Y and Z.

While we're looking up the URL, we'll look at another quick site.

Are there any other questions on author? On authoring?

M: [inaudible]

Jay Williams: Yeah, I guess I would have to say that *Virtus* is the one product I know that works. You know, my recommendations now are based upon — there are so few that are available, that it's hard to make an evaluative decision. Lots of companies — I'd say *Virtus* — you can walk out on the floor and somebody is going to tell you that their product is going to be out tomorrow and maybe their product will be better. Right now, *Virtus* will work, it will create objects and export *VRML 1.0*, so...

M: [inaudible]

Jay Williams: V-i-r-t-u-s. And both of the demos are on their site. They're also on the disk that comes with that book. At the moment, that's the most complete piece you can get that has all the basic beginning things that you need to get started is in that text.

M: [inaudible]

Jay Williams: Both. Windows, Mac and UNIX are all on that one disk.

M: [inaudible]

Jay Williams: Right. Good question. Before we drive around anymore, we'll go answer that question.

You see this VRML Futures form. Right now, there's a lot of discussion going on about where the actual spec is. Do we need to put it with the IF or do we need to keep going like we're going and work on things. How bureaucratic do we have to be? All of those questions. These folks are figuring out the answers to those questions. Not without input. One good thing about being so early in the process now is your opinion can be heard. I mean, now, being the normal meritocracy that the Net is, your opinion can also be ignored, but it can definitely be heard. You could post a list, you could talk to people on NewsGroups, you could do a lot of different things. These folks have all significantly contributed, in one way or another, to where we are today, okay? I mean, there are a ton of things going on and all these folks have created different things.

You look who's here: Gavin Bell from SGI, Brian Blau from AutoDesk, Rick Carey from SGI, John Hartenburg from OKI, Marbury from Microsoft, one of the guys from NETCOM — an academic; oh, my gosh — and several other people like Tony Parisi from Intervista, Mark Pesce and — I actually don't know who this person from Knowledge Adventures World is, but that doesn't mean — I'm sure they're important. I just don't know who they are.

These white papers — 20 August is what we're talking about here. I want everybody to keep in mind what we're talking about in terms of shortness of time that things have been going on. The VRML spec, I mean, really July was the announce date. In August, the I.I papers are coming out, okay? It's now November so, we've had three months to go through different pieces that are presented in these papers, so I.I is not very far away.

This basically goes through and talks about a lot of the different things that we had. I'm going to quickly run through one section in one of these specs, if I can find it. When these went to the printer, they got moved around, so please do not assume that the order that these are in is the order that they should be read. Check my Web site for a detailed outline, which I'll actually put up.

Let me talk about, from Tony Parisi's paper. That's the one that says VRML Proposal I.I — I.I. Proposal White Paper. He goes through and lists what the immediate tasks are in VRML I.I that they're trying to address. One, fix trouble spots and correct minor oversights.

Two, review currently-proposed extensions. There are a lot of extensions that are proposed. Some of these behavior things that we're talking about, and I'll talk a little bit about what those are in just a second.

Add useful *Inventor* constructs. That means some of the constructs — some of the ways *Inventor* is modeled and used in language, they actually want to include some more of those in the next specification, okay, to give us some more flexibility, in terms of defining the images; the way camera settings work, the type of things that we can do in the models. Add support for simple reality. Right now, complex reality is what most of the support is in there. Everything is designed assuming that you're going to make this hugely-complex polygonal model and you have to have all this lining and pieces and so you have to define all these things, you know, for creating different sections of the model. Discovery was made very quickly and early on that you could take a few polygons and do a heck of a lot with them, and so the discussion I was having earlier about having a few shapes you could combine and make other things has to do with that

simple reality piece, so that you can actually do particular things easily with small objects and create small files, rather than having the overhead of having to load everything that's in a huge file into the VRL.

Add API and behavior hooks. In programming terms, hooks are ways to link in other applications calls into the actual language so that if somebody wanted to create a specific extension — SGI, Microsoft, Netscape, anybody else — there's a variable function in here that can call to that particular function to allow more modular ability. That has to do with linking it with Java; that has to do with linking it with a lot of different applications that are out there.

Add location-independent name support. That's the issue of the file-naming structure that I was talking about. In other words, they have to be able to understand where the files are. You have to have an application-independent name support. You can't just depend on it to be in a file-naming structure that's on the SGI; you can't just depend on a file-naming structure that's used on Windows. It has to be independent of those particular environments.

Just so you'll know that the goal set here was: I recommend the following procedure. Do RFPs for each area in early September; have a I.I spec in draft on 11-1-95 — I haven't checked the site today; we'll see if we make it — and finalize by 2-1-96. Now, that's pretty fast for specs. And there's detailed explanations of each of the ones here. You know, collision hints. Web FX actually does let you use collision detection, so that you don't run into the wall and things like that. But, it's got to be written in the VRML and WebSpace doesn't even know it exists, and so if you write it for Web FX and it doesn't — you have one of those compatibility issues. And then there's a switch button that lets you cycle through things and things like that, and most of those are specified in this particular one here.

Then J.N. Hartenburg's quote : "If you're walking on thin ice, you might as well dance." So, that's his discussion of how they're developing the VRML standard. So, you can see that it's quickly putting all kinds of things into the actual specifications.

I know I went really fast, so I appreciate your putting up with me going very fast. Are there some more questions that I can answer? Yes, sir.

M: [inaudible]

Jay Williams: Right, and see one of the database front ends. What we'll do is we'll go to one. It doesn't actually function, at the moment, but it's a front end that you can actually see. I should really show you the Jerusalem City Hall model, too. If we have a minute, I will.

Now, you'll notice that it's 12.5 megabytes. That's 12.5 megabytes G-zipped. It's almost 40 meg unzipped, but it is one of the most detailed models ever done. I would show you WorldsChat, but it involves switching the machines back and forth. I urge you all — if you've got a Windows '95 platform available to you somewhere, go get WorldsChat, download it, pick your avatar and go walk around and play. You can actually go interact with other people, you get to choose whether you want to be a penguin or a one-eyed alien or yourself and wander around. Your name appears above your head, you get to have a little chat window open, you can go talk to people. I warn you that the conversations on there are different and I take no responsibility nor can I be sued legally for recommending that you visit said place.

Now that the disclaimer is gone, let me see if I can find the one I want here. By the way, somebody mentioned games. We could look at Westword, which we will, in a second. Let me see if I can find the...

M: [inaudible]

Jay Williams: Absolutely. Most of the people that are experimenting with those kinds of things are also experimenting with these kinds of things. This is a Clay Graham creation — yeah, yeah. Remember I mentioned the stock floor that moves? This is the actual creation of — the stock floor moves around, so the floor actually increases and decreases in level with the performance of the stock. It's a little lower right now, yeah. Did anybody notice that? Yeah, it is actually low. Frequently, it's been up around here. It's quite interesting. You can actually pick different views. Clay, of course, has a lot of views.

M: [inaudible]

Jay Williams: It adjusts to floor height, yeah, based upon the ticker results from the stock.

M: [inaudible]

Jay Williams: Oh, absolutely. And you can call CGIs. You can do any kind of the programmatic things that you'd like to do. In fact, one of the things that I did, I just have the little one that changes the streetlight color, depending on how many times my Web site's been hit. So, you know, I have a little space that goes in there and I have a couple of little streets, and I have a little streetlight. And the streetlight's really easy to make; three circles, a box. You know, not rocket science at all. And, you know, the streetlight color changes, you know, depending on how many hits the site's had a day, so you can just go over to the site and, you know, see how we're doing and things, you know.

M: [inaudible]

Jay Williams: I think he only updates it once a day. It has something to do with bandwidth and, you know, sending things back and forth and all those kinds of things.

M: [inaudible]

Jay Williams: The one thing that, of course, you can't do, notice, is go back and forward when you're inside, when you're moving from models back to back like this, which is a deficiency.

Oh, here's one that's created by CGI — there's actually a couple that are created by CGI. I'm going to get to the database one, I promise, but I want to actually show — notice this one. The light direction and sun position in the scene represent the real sun position in Warsaw. During the night, the city scene is limited by streetlights. Because of long nights in Poland, some people are not able to browse this scene in daylight. But, it's very interesting to show you the kind of example that you can do. I mean, travel log things — the thing at museums. Talking about going to the virtual museum. Heck, going to the virtual museum is sometimes a lot better than going to the real museum, because you can actually stand in front of the painting. Or the painting's not on loan. I tell you, I went to Rotterdam one time to see a painting and it was on loan. Boy, was I mad. Very nice, very nice representation. And, of course, you can go through the different sections. I mean, this is not complex. This wasn't even G-zipped, and this created it real time from a CGI file. I mean, it's actually rewriting the stuff from the CGI file, so you can get an idea of the kind of things that you can do. I mean, it's really amazing. When you sit down and start doing this stuff, the ideas just crank through your head, in terms of what you can do.

Other questions? This one was built with *Home Space Builder*. You can see that you can actually download the textures and see the textures on a particular thing. You'll see a lot of

different, you know, types of things out there. It looks like we're not going to be able to get across. It does happen. Let me see if Robin Hayes' Castle...

Questions? Got to be a couple more questions left. That's great. I like it when I answer them all.

This is just a quick little castle that you can slide through. See the different pieces of castle, walk through it, go up to the door. This door is obviously going to take you to a different spot, the gallery, in this case. Notice — did you see the wire frame redraw in the back as it came down? You come into the gallery, see some cool artwork they have hanging around. Nifty 3-D stuff.

Notice that this'll take us to places, right. Whoop. O-o-o-a-h. Pretty nice, huh? Notice it automatically shifted me to the examiner mode, so you can actually look at the art, move it around. Pretty neat. Notice the back function is actually working in this model. Obviously created by an SGI employee. Very nice models here. I mean, these are pretty neat. I mean, now we're getting into some real applications where new things are being created that didn't exist before or that you couldn't create, or if you could create, you couldn't see them in this kind of environment. You don't see this in your average museum. Again, you can see the use of level of detail. You don't actually get to click on it to get close enough to visualize the object. These are very fast. These are small. You see how fast these are loading. These are not stored on the machine. They're coming directly off of SGI's server. There's a tricky part of this one, you see, where it looks like it's bending, but it's actually not. It's very interesting.

There's a couple of these that they've worked on, see that? See the effect that you got of actually feeling the thing bend. It's not; it's all splined, but — it's not an interactive movement, but because of the shape of the curves, it gives you the appearance of it. Very interesting stuff here, so...

M: [inaudible]

Jay Williams: Ask again.

M: [inaudible]

Jay Williams: Right now, the *WebSpace* Browser is available on the SGI platform and on the Windows platform, okay. On the Macintosh platform, the *Whirlwind* Viewer is available, which can see some of the VRML files that have been created. I mean, I expect it to be able to see them all very soon. As far as other types of browsers, *WorldView* Browser, which was created by Tony Parisi is available on the Windows platform. It's included on the CD-ROM; the *WebSpace* is not on Mark Pesce's book, for a lot of reasons. *WebSpace*, it's on their site, though. You can actually go get it. TGS — and I guess, just to show you a few of the sites where you can go get some fun stuff, let's go look at some of those.

Virtual Maze Generator. This thing — I gotta show you this. This is another CD — ah, come on now. Don't tell me that. Try this with *Netscape 2.0*; it'll work, okay. It won't work with *Netscape*, this version I'm using. But, you can actually go to this one and it — you can actually do the user interface. You can actually specify the X and Z on the section. It'll actually go create a maze out of VRML, based upon that interactively. It's very nice.

M: [inaudible]

Jay Williams: *Web FX* for the PC. *Paper Software* is actually here. They're out on the show floor.

M: [inaudible]

Jay Williams: Yes, it's multi-user.

M: [inaudible]

Jay Williams: They're using a modified form of IRC for the chat sections of it. It's a rebuilt chat room. They may be actually using GlobalChat, actually, to tell you the truth. I think they did actually contract GlobalChat stuff. Let's see. I think we put it on *WebSpace*. Yeah.

WebSpace.sgi.com is your entry view. This is a Lightscape-created section, which — we didn't get to see any of those neat ones, but you can see them on your own. You can actually go in here to find out about all the different tools. *WebSpace Navigator*...and we'll take you in and show you all the different sections. You can actually find out all the different kinds of things — software availability, platforms it's available for. You can see the beta versions. They're coming out any second. These are the ones that are currently under development. Oh, I'm sorry. To find the particular one, you'll need to download from templates graphics software for the ones that are currently available. It's going to take us over to TGS now. *www.sd.tgs.com*. SD is their HQ. And you can actually go down and find all the things here. *Open Inventor*, by the way, for 132, is now available. It's 995 bucks, hey. I mean, we're talking some reasonably-priced software for creation of things like that.

You actually get the full *Open Inventor* suite. It's fairly robust. It's very good. So, you can find out exactly what all's in here. It goes through and discusses all the different pieces and parts that you can get. Let's see. Where's Getting *WebSpace*. They have a VRML authoring primer here; they have a bunch of sample scenes; they have a ton of stuff on-line to help you get everything up and running. They're very good. These are the planned releases, again, in more detail. Others will think about them after this is done. You can see the sections that are coming out. You can see what's available currently. SGI, Solaris, AIX, W-32 and NT and 95, okay? More fun and exciting stuff. Registration is 49 bucks. Come on, cheap. Please register.

I always encourage people to do that, because so many people don't. Obviously, there's a lot of different things you can do. Once you get on-line, you gotta go to Silicone Surf. Have you been? Anybody been? Anybody seen the 3-D version? I'm sure some people have seen the 2-D version. Gotta have a password. It's free, but you've gotta have a password. But, it's pretty neat. You notice the wire frames because of how far we are. It's telling us, hey, I'm trying to talk to the host, because I want to get him. Now you'll see it begin to build the level of detail, based upon the distance we are out. This is an interactive area. Multiple people can go here. You can post here. There are post boards. There are things you can do, see, run around, etceteras. The wire connection is slow here, but it is...we'll go ahead and drive on up while it's still drawing things for us.

Here comes the road. But, it's really good technology that allows you to do that, so you know that things are coming in those particular places and you can wait until they're done. You can actually go to the entrance...you can actually go to the gallery. Obviously, when you get up to the gallery, you going to find that there's a link there, which we'll go to, slowly. Ah, got to have a user name. I wonder if mine works. No, I think actually, I put the wrong one in. Yeah, it happens. I think they made me JW-I, actually, for some silly reason. If you can remember your password, you can go in. I can't. I have so many different registration join things running around that it gets out of control occasionally.

Obviously, the SGI site has tons of stuff and important things on there. You can find out all about different stuff. You can actually go find out about *WebSpace Author*. Let me see if they show the platforms that they're coming to on here. \$995 for *WebSpace Author*. It's going to be

on all WebForce systems, so for those of you that are WebForce users, you can actually get it as an upgrade. I don't know — I think it's a free upgrade, right? Yeah. Existing WebForce customers, free upgrade. So, in addition, if you get the Indy platform, you not only get just the WebSpace and the VRML pieces, you get all of SGI's cool Web authoring tools, which you can see out at their booth. I don't work for SGI, but they are nice, and you can do a lot of things with them. It also makes a good server.

So, other questions?

M: [inaudible]

Jay Williams: The Indy, I would say — again, that's kind of a tough question to answer. I mean, if you're on an Intel machine running, you know, Berkeley/UNIX or if you're on an Intel machine running Windows '95, it's probably seven times faster. I'd say that's about right.

Anybody else have an opinion on that? I always like to have other opinions. Pretty close, seven times? It's significantly faster, let's put it that way. The UNIX platform is going to exceed the performance of any Windows platform currently, including Windows NT.

M: [inaudible]

Jay Williams: A UNIX platform will exceed the performance of any Windows platform that currently exists, including Alpha MIPS, PowerPC, dogs, cats, hamsters, anything along those lines.

M: [inaudible]

Jay Williams: Yeah. I mean, it's an OS issue; it's not a hardware issue.

M: [inaudible]

Jay Williams: Oh, yes. It's actually hardware — it's designed to perform. When you walk up and see the video cable here, you'll understand. It uses a proprietary video connector, just so that it can deliver the kind of things — I mean, this is an \$8,000 screen that we're looking at things on here, so, you know...but it's a great screen. It's an LCD. It's probably the most expensive LCD panel you'll ever see. But they just reduced it. It was 12,000 last week. Next week, I hope they reduce it again. Then I can afford one.

Seriously, though, they're very good stuff. But you can get this kind of performance off of most other servers and, obviously, you can get a lesser panel and those kinds of things, so they're just gracious enough to let me borrow whatever equipment I like.

Other questions?

M: [inaudible]

Jay Williams: Say again?

M: [inaudible]

Jay Williams: Oh, yes. Well, they have the platform.

Well, thanks for coming, everybody. We appreciate it. Does everybody have my card and such?

TUTORIAL COMMERCIAL WEB DEVELOPMENT

SPEAKERS

Chris VandenBerg

Products Manager, Microsoft Online Services, Microsoft

Michael Bauer

President, The Internet Group

Jim Sterne

President, Target Marketing

Chris VandenBerg: [Hello, I'm] Chris VandenBerg. I'm from Microsoft, and I work in the Online Services group. Jim Sterne is the President of Target Marketing, and Mike Bauer is the President of The Internet Group.

I think what we're going to do is have about a four or five hour discussion, with a break, about some of the commercial Web developments. Pretty broad topic, huh? And pretty tough to cover in that time-frame.

We've actually been doing this kind of thing together — this is the third time now, isn't it? It seems like I've been doing this forever with you guys. But I guess we've kind of followed the whole Internet path. The first time was actually in BC, about a year or year-and-a-half ago, and things have taken off since then.

I would like to think that we've stayed current. We do have some relevance, I hope. Our employers seem to think so; or, in this case, these guys are self-employed and are actually quite successful doing this all the time.

Personally, I like to make this really interactive, especially since we have, as I said, an intimate crowd. So the goal is that we're going to talk about some things, but we'd like to make it very interactive, just like the Web is supposed to be. It isn't always, but the thought's there. So if there are things that are brought up, or there are questions, we want to make this fun. I flew on a red-eye to have fun here, and that's exactly what I'm here to do, have some fun. We always try to take that approach and, please, if there are things that you want to add or that we can do to make it more fun, let's talk about it.

Hopefully we can cover all these things, because we all have presentations. There we go, that's just enough so that if we are boring, you close [your eyes] just like that. It's our job to keep you awake and keep things interesting, so as I said, we're going to talk about commercial Web development, which is a whole bunch of things.

While I'm fixing this, Jim, why don't you talk a little bit about Target Marketing.

Jim Sterne: Let's see... Target Marketing is a consultancy that helps people figure out how to use the Internet — specifically, the WWW — for marketing. I started out a couple of years back. I've been on the Internet for about four years for e-mail, and when Gopher sites started coming on, where people could go and get whatever it is they need, [I wondered] how come nobody was doing it; I started to do my research and, about halfway through, out came *Mosaic*. Suddenly that was the answer, and it was obvious that it was time to do marketing.

I went to seminars and I talked to a bunch of people and read a bunch of books, and I found nothing that talked about marketing. When I finally found enough people who could speak coherently about it, I put them in a room and put on a seminar. That was about two years ago, and that started the ball rolling. I ended up running into Chris and Mike because they were very Internet savvy, very Internet marketing savvy — Chris doing Internet marketing for the company he was working for at that time, and Michael helping Fortune 500 companies do Internet marketing from the technical perspective.

I have a book available at the Wiley Booth in the exhibition hall called *The Wide Web of Marketing*, and hopefully, by the end of the day you'll be encouraged to buy it, rather than discouraged. You'll have an hour with me to make that decision. Michael?

Michael Bauer: Hi, I'm thinking about writing a book called *How I Hate the Internet*. We've been doing this about two-and-a-half years; we started out back in 1993, and we started out working on the [inaudible] network. Now, there was a business plan for that which couldn't quite justify a business case on the first time around; we had to sell so much advertising, it wasn't clear to us exactly how we were going to do that.

We actually started trying to sell advertising, and we'd go to the people and say, "You want to take out an ad?" They'd say, "We're not sure yet. We haven't measured it — let me get back to you." Something immense was in the cost per thousand for advertising, and this was the mind-set of people placing advertising. Other than NordicTrack, of course.

Jim Sterne: Okay, so you're the only person on the Internet who hasn't made money.

Chris VandenBerg: Okay, I'm not going to sell you anything, I promise. By the way, if I do try and do that, throw a chair at me. I hate that, that's not what I'm here to do. We are here to kind of talk about some of our opinions and thoughts on things that are going on, and if you find that relevant, we're all happy. If we create controversy, that's even better — I love that. If you agree with everything we say there's something seriously wrong, because we all have different opinions.

Some of the things that we're going to cover today... I want to kind of do a level-set, because it's so easy to get caught up in all the hype and everything that's going on here that we kind of forget how it all came to pass. It's very important to understand that, because you're trying to design for the future; it's really tough to design for the future when you don't understand some of the key aspects of the past, because you really don't want to repeat the mistakes.

That's the only reason to bring those up, but we also want to talk about the fact that there are some very key opportunities going on right now in terms of access and overall better usability, which are creating the opportunity to really engage people.

The term I'm hearing now is "grab 'em by the eyeballs," It's kind of disgusting imagery, actually, but it does have relevance to what we're trying to do. I'd like to talk about some of the technology, though this is not a technical outline session. If you want to talk about which switch to turn on, it's not going to happen here, although Mike probably is the closest to being able to do that. But we're trying to say, okay, what are the potential solutions and what are the goals — that's really how I look at it — and talk about some of the security issues.

I'm going to focus on dynamic content. My personal goal for the Web is being able to address this rather nebulous concept of "narrowcasting." We're doing a whole lot of broadcasting right now, throwing a bunch of stuff up on the wall and hoping somebody likes some of it. Maybe this is not the best way to go, and maybe there are some better ways; because really the goal here, if the technology can emerge, is being able to address a market of one.

For most marketers it's very scary to think in those terms because you're trying to make it a very personalized experience, and you clearly need help from the technology. But if you can do it, the potential for success is much higher than just playing the numbers game of throwing it out there and hoping that some of those 40 million people actually are looking for what you're trying to offer.

Mike is going to talk about the whole design process. His company focuses on this and, as he referred to in some of the sites he's done, they have a huge amount of experience and they've done some very cool sites. It's interesting to watch how Mike's business has kind of mirrored the whole growth of the Internet. Clearly, they've benefited from doing some very innovative things.

I think we want to address some of these issues, to try and say, "Okay, how much does it really cost? What do you get for that? How do you make the decision in terms of whether you want to do it yourself or you want to have somebody else do it?" Because to make people buy — I'm a products manager, and I also have to evaluate how to make people buy — is it a competency that I want to bring in-house?

Now, Jim is pretty good. Jim and I have a relationship and I really enjoy listening to Jim because he brings his rules to this whole thing and makes sense out of it for me. I always learn something when I hear Jim talk about these things. I think he's going to go over these; I'm not going to in any way try to steal his thunder, but I do suggest that you follow [along closely] because Jim also can be very angry, and we want to make sure we don't make Jim mad.

At the end of the day I think we're going to talk about where we all see things going, and I hope this really stimulates a good conversation because the Web has grown so big — and all the Internet hype — and there's so many different focus areas that there's no way for anybody to kind of say, "Okay, here it is, there's a ribbon around it, away you go."

There are going to be different areas where people have different areas of expertise, and we like that. We'll always learn something from that. Hopefully it's the synergy of everybody in the room, and somebody comes away with something that they didn't come in here with. That is the goal.

I've got a bunch of strange [inaudible] the copyright law. I've given you my handouts; they are copyrighted by the owner. The lawyers make me say that and it's very valid. By the way, if you're doing this, please be very aware of copyright law. We've created some very cool tools to make theft very, very easy, and we all have to be aware of that and not use it in that manner. We still have to respect the fact that there is intellectual property and there's copyright — although, quite frankly, one of the issues is that the rules have not kept up with the technology at all. We're not going to judge that too much — I know I'm not — but that is a continuing conflict, and I'm still waiting for the precedent case to get settled where somebody actually goes to jail for really taking some other stuff.

Everybody's seen a million of these graphs. Has anybody gone to Interception during the show? So you've seen these in every session, right? You have to; it's required, they make us put these up there so that we can buy into the whole thing, too. The interesting thing, though, is that a year ago, when I got these from the Internet Society, it was only 100 million. Now in a year they've upped the projected total for the year 2000 to 124 million.

Actually, in one of the publications I was reading on the way up, [the author] was saying that it's actually going to be a billion by the year 2000. I'm not sure what Nick's smoking. This is nuts, this is ludicrous; maybe if in the year 2000, if 800 million come on that year it might make it, but let's be realistic.

The fact, though, is that all this fun traffic that we're generating, all these new applications, all these things that we're putting over this thing that we call the Internet — it's very important, if you're trying to evaluate actually doing something that is innovative, [to realize that] the Internet today is a finite resource. This is not something we talk about, ATM and all these other fun things... I've got news for you, it ain't out there yet. The reality is that there's a very finite resource called the Internet, and it's handled by MCI, Sprint, PSI, and AT&T and all these people. There's finite capacity out there.

I've chatted with Vince about some of these things. Vince is known as the father of the Internet. I don't if he even likes that or not, but he does have some great insights and opinions. [We talked about] things like the new applications, real audio — which I'll talk about later, which is also really cool — but Vince says it's also a real pain because he works for MCI, and from the standpoint of network congestion it causes serious problems.

So one of the things that we all need to be aware of, and I like to bring up in this session, is that we need to take a realistic view about the Internet.

Not that you can't use it in that respect, where you can push the envelope; just be aware that the backbone is something that you need to be concerned with. You can come up with a really cool application that does some marvelous things within your environment and maybe even on your corporate LAN; as long as you're just going to use it internally, that's a fine idea, have a good day. The point is if you then say, "This is really cool, let's share it with the world," and it needs 300 or 400 kilobits to run well, you can assume that everybody in the corporate side is going to have access to it, and some will.

But you may see serious degradation, especially at noon. I've given up trying to use the Internet between 10 o'clock in the morning — I get in at 5 a.m. Pacific time, and I do everything I need to do between five and seven, because after that it becomes unusable for almost everything I need to do. And I turn into a pumpkin at 10 o'clock at night, so I can't stay up until three in the morning, when some people do this stuff. So just be aware that there are real constraints as you're trying to design things, and look at how to use this resource.

Okay, some of the trends... I mean, this is kind of my role on this panel. I get to talk about things that they don't let me talk about at work, so it's kind of fun to look at some of the things that are happening. This is something though that I am directly affected by: the connectivity.

In the U.S. we're in great shape; all you have to do is walk out on that show floor. What's it down to — \$9.95 a month unlimited usage or something like that? You can get Internet access, really cool, and if you even want it to work, or work reliably, it'll only cost you a couple of bucks more. But normal market forces are kicking in, where you decide what kind of service you're willing to pay for. That trend, by the way, is going to be extended pretty dramatically when we actually have an infrastructure that can prioritize traffic.

One of the things you can't do today is video-conferencing over the Internet — and before somebody says CU-SeeMe, which is fine and dandy, it's a nice educational application — but try running your business on it. I'm sorry, it's not a real tool for business, and today the backbone wouldn't support it anyway. We need to be able to prioritize things.

Connectivity in the U.S. is probably two years ahead of Europe, and maybe even longer in some other parts of the world. Having said that, I think when we get to the afternoon I'm going to talk about some of the things that I've seen internationally, where they're not trying to keep that linear separation — they're trying to use this as an economic weapon, if you will, for positioning their countries much more effectively to communicate. I see them really putting in the effort to leapfrog and come on much more aggressively with widespread affordable connectivity.

Widespread connectivity in Japan — it's typically \$12 an hour, but it's widespread and you can get it in a lot of places, and it's \$12 an hour. So the two have to go together. That's certainly one of the trends that we're benefiting from here in the U.S., and it's starting to get better elsewhere as well.

The biggest thing has obviously been the tools, having something that you didn't have to say — like "[auk-/v,]" and all that gunk that people who came from the UNIX environment, like I did, were very comfortable with. That's why there were so many Ph.D.'s on the Internet; this was not an accident, because you almost had to be at that point to understand how to use the

thing. But it was designed for that, so that was okay. Certainly, the work with *Mosaic* has changed all of that, and that's probably one of the biggest things, the getting away from tools that were designed by technical people for technical people. I'll use a term of endearment a little bit later on that maybe some of you can identify with.

The interesting thing, though — and this scares the hell out of the telephone company, by the way, and I always like to do that because some of them maybe need the hell scared out of them — but the applications traditionally have been driven from the telephone company; they offer you a service, they test it, they deploy it, they make sure it scales, and they charge you five times what they should for it. And away you go.

The Internet's very different. The Internet says, "Okay, here's a transport mechanism, you come up with all these other little things on the outside and develop [as you] need applications." That's why there's so much cool stuff going on, and that's why it scares the hell out of the phone company, because for [those] two reasons they're no longer driving the applications. If they're smart they can figure out how to leverage this, because it's driving traffic across their network and that's their core resource, that's what they have as an asset. Some of them, though, are very frightened about it; they're trying to control it. They're looking at this saying, "Geez, this is not how we do business." Because the Internet says two things no longer matter: distance and volume of traffic. It doesn't matter — just sell me a flat-rate pipe.

But for me, [this is] very interesting in the U.S. I think some people are really struggling to build new business models because those two things — distance and volume — are what they've built their fundamental business models on. That's why you see a lot of the RBOCs coming up with Internet services. AT&T, MCI and Sprint have all had these things, but they're being elevated from kind of the skunkworks over on the side of the company to something very, very important. I know AT&T with John [Petrillo] has done this recently — realize that there's a fundamental shift going on, and if they don't figure it out it's going to be way too late, and they're going to be operating with the old business model and they won't compete.

[About] connectivity in general — a lot of people, as I said, build really cool applications that run great on the corporate LAN; and in some cases you can even get away with requiring ISDN, as long as you have a fallback. What 98% or 99% of the people have out there are 14.4 modems, [and that's] moving to 28.8 modems, but believe me, we've done a ton of market studies and you can't even assume a 28.8 modem.

Depending on what your goals are, if you're trying to reach the mass market you've got to assume the lowest common denominator. Just as an example, we tested MSN [the Microsoft Network] with a 9.6 modem — it's ugly, please don't use it with that. I can't use it with that. I do use it with 28.8; they offered it to me and I said, "No, I want to get a feel for how it really is with what I think is soon to be the lowest common denominator." Modem prices are coming down really quick, so make sure that you test your concept against the infrastructure that's in place — it's very important.

Otherwise, you can do some really cool work — kind of like the MIT Multimedia Lab, they do some dynamite stuff — and as long as you've got a T-1 running to your house you're going to love it all, you're really going to like it. But that's not realistic, and that's certainly not where all these people... I've seen the advertisements in *Internet World* and some of the other magazines, with the guy sitting on the Rolls Royce up there saying, "Make millions selling Internet access." I guess those are the guys that are hoping everyone gets into those applications so they can sell you the big, fat pipes. But just be aware that there are choices out there. ISDN isn't even a good assumption because the RBOCs, quite frankly, haven't got a clue on how to market this thing — it's still too hard, it's still too complicated. So just be realistic about the infrastructure is my message there.

The tools are really cool, and the big change, obviously, was getting away from requiring a lot of knowledge about the network. There's one network that's pretty much ubiquitous, and it's that little thing with the hand-set and the keypad. How often, when you pick up that phone and you start dialing, do you think, "Oh, okay, well, this goes to the central office switch, and central has a switch and they're taking the number and..." Do you care? It's transparent, it just works. That's how you know technology is mature — it's invisible.

The Internet is not there today — it's a lot closer, with point-and-click tools — but it's by no means there. It's still got a long way to go and we're going to see a lot more integration. But, using the whole point-and-click metaphor, it's taking away the requirement of actually knowing anything about it. You used to have to know where you wanted to go to start a session; that made it a nice closed little club, and all those people that knew felt so smug. But that's gone.

So really, when we went from this whole model of the "UNIXcentric," for the technical people — hey, if this is what you enjoy then have a nice day, that's fine, but that's not the mass market. The general reaction to something like this is that they can't deal with it; it's something that potentially is a problem. I think everybody really prefers this whole point-and-click architecture.

The challenge here is that if you have access and usability you have some very nice things coming together, so you can reach a lot of people and they can actually use the tools to get to some of this content that's out there. Now, the real challenge is finding what you want and making it usable. I remember about two years ago when I used to get on and read the "What's New List" in NCSA every morning. That was possible back then, there weren't 18 million entries in the thing and it was still pretty cool to see something new come up. Does anybody still do that? I actually did it for old time's sake the other day. I got back onto "What's New" and it's still there. I was really surprised that it still kind of worked.

But, clearly, now that the focus is [on the fact that] we've got this really interesting resource, and we have tons of material out there. I can buy a grave site in Finland across the Internet if I was of a mind to do so. I'm not really interested in that, but it's kind of interesting that I can do things that are that esoteric across the Net; that means most of the mainstream stuff is pretty well covered. I can buy a car, I can do a lot of other things.

Now the challenge is: can I find ways to integrate all this information in a usable form into my everyday life? Because that's a mass-market technology. If I'm just surfing around and having a good time, that's fine. I think everybody gets on — we've done studies that look at the new Internet user, and everybody's blown away for about the first three or four days, and you see people huddled up against their computer for 16 hours straight. But that wears off. Am I the only one that's kind of just burned out on that? There's times for that, but it's recreation.

The key is that I know there are some great things out there that can help me in my everyday work and home life, if I can only find them. So that really is the challenge right now — getting away from just the browsing model. A lot of different organizations and a lot of different content providers are taking different approaches. That's the nice thing, once again, about the Internet model — it's so open that a lot of people are taking different approaches. We'll see which one works because the mass market will make their choice and it will be very clear that the switching costs on the Internet are zero — it's a click away, so you'd better do a good job the first time. More on that later.

We're starting to see things like peer group alignment, where people say, "Okay, if you're interested in these types of things, try going over here." You know, Yahoo tries to break things down by categories and interest areas in some cases. From a marketing standpoint, trying to give people interest bundles based on what they've already done is a very, very interesting concept; that gets me away from just this broadcast model to at least a more focused, multi-

cast model. I can find all the people that are bicycle enthusiasts if they frequent pages that are bicycle companies. The problem is that the Internet today is not well suited to do that. You can track very clearly what a person does on your site — but what about the other 200 that they browsed? You can't do it, and that's, by the way, one of the values I think that the commercial services are trying to position [themselves as being able to do].

[There are] some really sticky privacy issues, and if we don't get into spirited discussion during that, then I'll give up. But that's one of the really tough issues that, as a content provider, you have to be very aware of, and as a user you also tend to have some strong feelings about. But the only way for somebody to find out what you like is by looking at what you do or asking you to fill out a form or something like that. They can't learn it by osmosis, and so we've got this battle with privacy versus the ability to try and find out and focus the message more clearly.

Clearly, a bunch of people are getting into trying to use this whole resource that's out there called the Internet. It's very interesting that some of the figures that I've seen are that 60% to 70% of the new Internet usage is coming from the commercial on-line services. I would like to think that part of that is because they're making it easier to use. Some generic service providers don't provide a lot of guidance, and for the technical user that's fine, that just gets in their way; but the mass market still needs some help — "Help me use this thing." It's not intuitive enough to say, "Here's a pipe, here's a browser, go nuts." It may work and it may not; it leaves a lot to chance.

I guess that the point is that the commercial service providers are trying to offer a more helpful experience — some would say maybe a managed experience. I'm not going to get hung up on the terminology, but there's a lot of growth coming from the commercial services, and right now we'll see how much of it is hype. There are some figures, by the way, on on-line services — just kind of as an aside — that we're starting to see a bunch of people that are kind of "churn" factor. They spend a free three months on one service and then they go spend three free months on another service and they just keep making the circle, and they never pay a bill. The thing, though, is that they also lose their e-mail box every time, and that's kind of a big thing to lose. That's one of the big benefits there.

Taking a look at what's been going on — and, by the way, you guys are way too quiet, so we have to change that — this is what we started out with about two years ago. I don't know how everybody else found out about *Mosaic* but I was actually reading *Info World*, I think, and Bob [Metcalf] said, just as a side note in one of his columns, "Hey, you should check out this really cool FTP site called NCSA, they've got this neat thing called *Mosaic*."

I downloaded it and it was really cool, because it was images and there was a little picture of the speaker, and I clicked on that and it took about a minute and a half to load the clip — it didn't come over too fast, but that was very different at the time. I could click on text and it took me somewhere. It seemed like from that point we had a lot of outboard viewers; you download a video clip and something else gets invoked to play that. There was a lot of proof of concept going on, and clearly, Tim [Burslee] had a very good idea. I think a lot of other people made it a reality, but *Mosaic*, from the front-end standpoint, really started the whole thing running. But without the infrastructure *Mosaic* is pretty much useless, so it was all the Web servers behind it that really added some impact to that thing. But it was still really hard.

I remember the first Web Conference, which was really a technical get-together for all the "Web-meisters." It was clearly all technical people. I came from that environment, and I can spot the technical people — I mean the extreme technical people. It's like InterOp used to be in the mid-80s, a lot of Birkenstocks with socks because it was really cold; but the point was it was really hard and difficult, and you had to have that level of expertise to make anything work.

I would like to think that we've kind of moved to maybe the next stage now, where we're trying to extend this concept. We've proved it works, [we've proved that] you can do

multimedia, you can do a lot of stuff; now what do we want to do? We've proved we can do a lot of things, so there's a ton of technology. I guess that's what I came away with from reading all the trade plugs; there's a bunch of stuff, a job is out there, real audio [is out there with] *InternetPhone*, you have MPEG, video — all this stuff is out there, which is really cool. Once again, a lot of groups are focusing on particular areas, and that's fine. There's push/pull technology, all these things, and if you're going to do design, I guess my message is this: please be clear about what your goals are first, and then drill on those technologies that you think will help you get there. Be prepared to continue to update that because this stuff is changing in real-time.

Actually, I used to have a video that showed kind of the history of the PC from 1977. I think was the first... These guys have seen it so many times that they made me stop bringing it, but it took 20 years, from '77, almost 20 years to get the PC to the tool it is today. And it's taken two years to get the Web where it is today, which is an incredible compression of product cycles. So things are changing.

The first one of these we did, people were saying, "What about security?" So people went out and solved security. What's the point? All these things are going on, so the interesting thing is that we're now focusing on trying to come up with ever-more unique content, but it's still broadcast, by and large, and it's still really hard to figure out what groups of people really want. It's also hard to change it on a dynamic basis, based on what those people like.

When I show you an ad, if I know you're a bicycle enthusiast, it would probably be nice if it were an ad for a bicycle company; [an ad for an] FTD florist maybe isn't what you're looking for at that time. But that's the power of the technology, if we could just work out some of the details. It's just code, after all. That's what we say at Microsoft — it's just software. But it's really hard software. That's the reality, and there's a lot of work going on in a lot of different places to solve the problem.

Now we're starting to get a lot of people that instead of taking their newspaper and putting it up on the Web... I think sometimes they just scanned it in, it was just ugly. Now people are saying, "This is a new media, we have to throw the old rules out. We have to try and figure out what's right for this media. We have to do new things." Maybe there's some reusable content — that's kind of a buzzword du jour in the content provider circles — but re-purpose content, I guess, is the appropriate terminology.

The point is that just re-purposing content without changing and adapting it to the new media is kind of missing the point of the new media. So unless you're just putting things like reference material up, which doesn't gain anything, if you will, from adding capabilities, you might want to look at trying to view it for the new media.

Technology is still really cool; just walk into the Sun booth and they'll tell you all about *Java* and all that stuff. But we're starting to get the idea that just broadcasting it out and hoping something sticks might not be the best way to do it. It's "sub-optimal," I guess we'd say. The goal here is — once again, when it becomes mature — is that you can just focus on the goal, you don't have to be a technical person to make it happen.

How many people in here know HTML? How many people have vowed they never will, and say, "Sorry, I refuse, I'm not doing it, it's not my job, and the tools should be smart enough to do it for me." Now, for those of you who do, that's great; I mean, clearly you're doing things today that you couldn't do if you didn't know that, and that's fine. But the tools are just not mature enough, and you still have to work really hard to do cool things.

I guess the point is that when the technology disappears, when it becomes much easier to be a designer and not an engineer, then we're going to see a real explosion, even more so than you see now — and the whole personal Web page thing is the first stage of that.

Ideally we'd like to get to the point to make a unicast message — I have some view of you, the user, and you've agreed that it's okay for me to keep that, and I can focus the material on what you find relevant and maybe let you even customize how that material gets to you. You get to have it your way, just like Burger King says.

Any disagreement? As I said, we're way too quiet. Is this nuts, am I smoking dope? I am? Okay, how come?

M: [inaudible]

Chris Vandenberg: It's still really hard to create extremely unique stuff. They tend to use a lot of templates, [the ones] that I've seen, and I try to keep up on the tools.

You're right, they've made it easier. It's not back at this first stage, where you had to code line-by-line HTML; the editors were ugly, the coding was ugly. Now people are starting to add new extensions — we won't mention any names — but while doing that we're trying to do cool things. It's not a conspiracy. Everybody's doing it, trying to add cool things, because we're trying to offer an ever-more unique experience. That's how you grab people by the eyeballs. But, in my opinion, it's still too hard; it needs to be easier to allow a designer to not have to learn the underlying language. It's kind of like making people learn assembly language to get something done on a computer.

M: [inaudible]

Chris Vandenberg: Okay, the view that the Internet is somehow a threat is personally incorrect. I work in a group where that's all we do is Internet. But from the generic, service-provider standpoint, anybody thinking that a monolithic data center model works against the Internet is nuts. You could never get all the resources and the content that the Internet has; you couldn't afford it, first of all, and there's no way that you could keep up with it. It grows exponentially. I think now all the service providers have seen that, and CompuServe and everybody's got "Internetcentric" services.

M: [inaudible]

Chris Vandenberg: You're right. I guess my point is, yes, the Internet is the thing — that's not the battle to fight. The challenge is to make it as useful as possible. It takes a lot of people; it takes software groups; it takes people creating services; it takes the telephone company scaling the backbone so that when somebody comes up with something cool it will actually run, it'll actually run during business hours. What a novel concept — from business to business.

And it's a problem right now. But I don't disagree with you at all; I think everybody is struggling to be much more Internetcentric. But certainly I can go out and find thousands of pages, and if I check the date on those pages they're probably going to be sometime in late '94 and nobody has touched them. Now, a lot of groups have changed them, but some people put it out there — it was information dissemination, and to the extent where they accomplished that, great. But did the information not change, or did we just decide that it didn't reap millions and we're not driving the Rolls Royce now? I don't know.

It's [a matter of] trying to look at what we're trying to accomplish with that, but the interactive ability initially was very limited. You chose where you were going to click, that was really your interactive ability. You could fill out a form maybe and ask for some stuff to be mailed to you, but interactive was "I want to go here and I don't want to go down here."

[Tape change]

Chris VandenBerg: ...on-line connection. I've got a wire to you with maybe a 28.8, maybe a 14.4; why don't I use that wire to give you stuff now, this second's information, however relevant that may be, and let you make that choice? I think we're starting to see more of that now, but it's a slow and painful process; and, once again, the tools are just starting to come out to allow you to do more things with the on-line, real-time connection you've got with people. It's kind of [a matter of] things meeting in the middle.

M: One of the things we're faced with in publishing is a whole paradigm shift, where people traditionally have published on paper, and it's static and it sits in the warehouse and you box it up and ship it fast, and when we want to change it two, three years down the road, we do a new addition of slides. But all of our editors' brains are feeling scrambled; they all say, "I need new data, I need new data, and I need it now, or yesterday." They can't move that fast yet. They're still having trouble rearranging the way they think about it because they're used to getting a manuscript and working on it for six months. I don't have six months, I've got six hours.

Chris VandenBerg: It changes the product cycle somewhat, doesn't it? I mean, it changes product cycles in much more than just the software industry, although the impact there has been extremely dramatic. But it changes product cycles in a lot of ancillary areas that maybe people don't think about as much. But instead of publishing the whole thing at once, maybe you have to do updates to a particular chapter, so that you're just plopping new code onto server. It's very doable as long as you can get people thinking in that mind-set.

M: That's an important point, too, because you haven't actually started to integrate all of your customers as contributors. To me that's a magnitude-of-order problem, dealing with that.

Chris VandenBerg: That's very scary to some people, too.

M: Isn't the other side the technical side, and the fact that we don't know how to technically manage them? How many times now do you go to links that are down, that are built-in? Well, once it really becomes dynamic, how do you manage all of that?

Chris VandenBerg: We're starting to see some better tools, though.

M: That actually becomes part of our problem, too, a person who's using our intellectual property. We need to have the technology on the back end and we don't have the resources to build that technology today, so we have to start with this semi-dead stuff. Everybody just banged down the door to see what book we have published this month. We don't have the resources to put this kind of technology in place to get that dynamic between ourselves and the professional student.

Chris VandenBerg: Right. That's an interesting challenge, but I think that if you're wondering what in the next six months will be one of the hot topics, then information management on the server has got to be one of them. We're starting to see a couple of products that every night, at midnight, it goes through and checks all the links and flags [to see] if something moved. Keeping track of the data in a data warehouse fashion married with the capability for

dissemination of the Web server is really what a lot of people have been talking about. It's just starting to appear.

I read about — I don't remember the name — but there was one product that actually did a structure of the links and told you where everything was, and actually did automated management of a lot of that. But I know a lot of groups are working on that on a variety of platforms, and to make it easier, so you don't have to manage it, it just kind of says, "Okay, here's where things moved," and it lets you move them into virtual server farms.

I like to pick on BofA — Bank of America — because they're actually such a good example of change. Their initial Home Page was the Golden Gate Bridge, and it had a couple of big buttons. The first one was payments; how very appropriate for BofA at the time. Then the next page — and I showed this to Jim and Mike in another session we did — was a much kinder and gentler BofA. I think they got some comments from people who said, "Yo, you might want to think a little bit about trying to be more personal; we're your customers."

The nice thing with the Web, of course, is that it's a great feedback mechanism. Please read it. Everybody who has that "Contact the Web Manager" message... I actually will do an occasional test where I'll send a little comment, maybe it's three-quarters of the time I never hear back. Either they didn't read it, or maybe they blew me off because I'm from Microsoft — that wouldn't surprise me. I mean, they're fair comments. I don't try and arouse anybody, and it's just kind of a test for me to see who reads it. With the majority I don't get comments back. So I hope everybody here does this and reads it, because people are telling you what they want, and that's huge. You would pay big bucks for that in any other situation, and they're doing it free.

So anyway, BofA has evolved their whole presence, and it's really an interesting phenomena. Now they're so customer-focused: "Build your own bank, this is all about you." Now we're starting to get into the concept here of a narrowcast, where they're saying in a very personalized approach, "Tell us something about yourself, the old traditional marketing stuff that we're trying to learn, but in a non threatening fashion." And if there's a benefit for the user, the user will make a choice whether they want to take that chance or not. But it's very interesting that they've gone through at least a half-dozen iterations, I think, of this page that I've seen. So it's been a very interesting bellwether of the evolution, if you will, of Web pages. I think they're on a very interesting track toward personalization.

I always have to show Sun because they have very cool Web pages — they do a great job. Actually, Sun is one leaders in internal Web usage, I think. They have a huge system internally for things like employee procedures and processes in terms of filing your travel reports and all this stuff that's traditional employee administration. It's all on Web servers internal to Sun — a huge amount of stuff.

They've kind of taken the approach of using Sun as an internal development environment, and then obviously pushed it out. They're doing some cool things, and they've also gotten away from being the page with the most icons on it. They held that award for about a good year, I think, hands down; they had about 40 icons at one point, and that was great. You could tell originally they did them for those nice, big Sun workstation screens.

I've got news for you; my little laptop doesn't do that, and the bottom third will always be cut off. So the message there is always test, once again, for the lowest common denominator. Take a laptop with a ratty screen and make sure what you're doing looks good and works at least in some form or fashion. If you're missing the key message... Let's say your particular marketing message is outbound marketing, and part of the page is a call to action, and you've got a button saying "Click here for our great free offer." If that button just doesn't appear on the screen, that's a bad thing. You will be sad. You need to take a look and think about those things.

We all take it for granted, especially with those screens that are 8 1/2 by 11. You get really used to seeing it like a page, and then you go out in the real world. My recommendation is please go out in the real world and see how it is.

W: [inaudible]

Chris VandenBerg: It's that lowest common denominator issue. I'll add another story from my previous employer, which had a corporate logo, and the color in that logo was a particular blue. It wasn't IBM, it was another stolid corporation. They paid a lot of money for that blue, they had it registered, and damn it, every screen in that company was going to have that blue. It's impossible, you can't do that, because each PC renders the color differently. But corporate PR just could not get over that.

Clearly there's a resetting of expectations and understanding when you start moving into these models where you're doing new things. You're not printing it on a paper where you have absolute control of how it looks. I shudder to think what their reaction would be when we say, "Okay, the front end lets the user customize it."

We used this, by the way, for a lot for recruiting, so I will say that if you're a corporation looking for good Web uses, recruiting works very well. Obviously we're a good fit because we're a software company, and the people on the Web are by and large fairly technical — although it's much more mass market now than it used to be — but then again we hire people who aren't software designers. I'm just saying that if you're in a corporate environment and you're not using the Web for recruiting and trying to draw good people, which is probably one of the hardest tasks in a growing organization today, you're missing the boat, and you should be using it for this.

Depending on what your business is, our experience has been that it works extremely well, and you get very well-qualified people. We're starting to see a lot of on-line resumés that are HTML and that do really cool things. We hire a lot of people who do really cool things in their resumés; they're slam dunk because you know that they know what they're doing. As long as you can get a feeling when you're interviewing that they really did it, that they didn't pay somebody to go out and do a good resumé — but I'd even give them points for doing that and put them in marketing, because they're product managers, and they did a make versus buy, and they bought. I can live with that. But I definitely strongly recommend you use this; it works very well for us, and also we're always hiring if you're looking for jobs.

The entertainment industry. I'll turn my sights to something that's a lot more fun. Because I kind of like *Seinfeld*, and they have really pushed — the entertainment industry in general has really pushed the envelope, in many cases, in what you can do. And maybe it's because they marry so many of the technologies; they're more into the dynamic nature of the content because of the broadcast media, whereas the print media has been static by nature and their real challenge has been, "Okay, how do we make this thing come to life for multimedia?" These guys [in entertainment] are saying, "How do we kind of de-tune it from what it does on television to grab people here, knowing the limitations of technology?" It's a completely different problem, a completely different mind-set, but they've done some creative things and they've thrown various multimedia in there, if it cooperates.

They've done this kind of thing — and I think they've done it very well — to give people a feel for what's going on and to show that they're leading the way into the new generation of multimedia and all that. You kind of expect that from broadcasting companies. I think also they're scared to death of being left behind, so they're trying to make sure that they take a very pro-active approach to this whole thing.

Actually, the movie industry has done the same thing. I don't even want to go see a movie that I don't preview somewhere, and the only problem is that I can't see enough of it to really make a decision. Everybody puts in those trailers that you see in the theater, and the movie always looks really good in those trailers, and then you get into the movie and it just doesn't live up to the trailer.

MasterCard is another one that I think has done a really good job of trying to offer value. I always bring them up because they're a good example of supplying a lot of other things that are completely unrelated to their credit card business, to kind of endear themselves to people on the Net. That's a good approach; there's nothing wrong with that. They add real value.

But the other point here is that from a very pragmatic design standpoint, it doesn't matter how much you put on your Web site. Wouldn't it be nice if a person who said, "Gee, I've found you and I've wanted to ask this question..." — and they don't want to wait for e-mail, because even if you have a very, very conscientious Webmaster that does read all those things and get them right back, there's some delay time in there. But I think what we're seeing is that now people would rather kind of say, "Hey, are you there?" and actually have someone say, "Okay, what do you want?"

The technology doesn't really allow that today. There are some things that you can do; you can use *InternetPhone* — and once again, yes, as long as it's not between 7 a.m. and 7 p.m. But it really isn't the kind of personalization. You can't cover everything somebody's going to ask — it's impossible. And right now, even if you had to give them an answer that was completely unintelligible, at least they would get an answer; but now they kind of wait for e-mail. We've seen a lot of people that ask questions that aren't in our knowledge base, and we'd love to put the entire knowledge, or the aggregate knowledge of all of our people into the knowledge base. But it's impossible, you can't do it. And that's the issue of unicast and trying to offer a more personalized view; it's an incredibly huge challenge to offer that kind of capability.

I think that the point I wanted to make by showing pages like this is that we went from fairly static pages — where people put things up and they just kind of lived there for weeks and weeks and weeks, even though things might have changed — and then we started getting into the periodical, first the monthlies and then the weeklies, and we started seeing that this was a very good way. They could change the content relatively painlessly. It may take them a couple of hours to re-publish the paper; there's a couple of problems with that and it's a basic limitation with HTML where design and content are one and the same. That's kind of a fundamental flaw, and a lot of people are working to solve the problem.

We went from this model to where we had things that were different every day, so we're starting to offer some sense of change. We've got an on-line mechanism to try and get people back, because if I see it once and I know it's not going to change I probably won't be going back unless it's some critical reference material, and I haven't found a whole lot of that in life. Life's too short and there's not enough time to do things. I do read Dilbert every morning, this has made it very easy to get my Dilbert fix. My mother is very disturbed that Pac Bell has fired Scott; that seems somehow unjust.

It's an interesting fact that now we've gotten to the point where things that do change daily are expected. It used to be a real surprise when you went to a site and then the next day it changed. Well, now, if you don't do that, forget it — you're not going to get them back. And that's the whole key — you've got to make sure you get them the first time because when you lose them, that's it.

Trying to pull a lot of things together, making the content change using some cool tools — it's all part of a very integrated approach to make it interesting and make it engaging. There's a lot going on in the technologies. I don't profess to be an expert in the technologies like *Java*

— Sun will do a much better job explaining it than I will. There are some very interesting things going on there, like the ability to actually download components potentially to do things. Some things are further along in the process than others, I will say, but the goal on all these things is user-directed — we've got a tool set and you decide what's right for you.

Push/pull technology, keeping the experience fresh, is the goal here. I mean, all of these are doing the same thing, keeping it very fresh, keeping it very immediate, so people want to see it every day because they know it's different. Some people, about six months ago, were saying, "Every time you log on we're going to change the background." I tested it a couple of times to make sure they weren't lying to me. Once again, it kind of got old after a little bit. And fundamentally, the information on the page didn't do much for me.

So technology is some nice stuff; just make sure it fits with your goals and make sure it enhances what you're trying to convey. That's really the key. Ultimately, though, what I would like to do is have some narrowcast mechanism; but if you don't know anything about me, it would be impossible for you to say, "Here's what you will like." It's going to be really difficult, and it's a huge challenge right now in the industry.

This was constantly changing for a while — the fish camera that took a picture of the tank, and everybody got on. This is nice but this is one of those things that I put in the category of "not essential for my everyday life." I guess it was somebody's idea of a good joke, but that's not change. I think change is something like *Java* where there are things going on, as long as, once again, it helps you achieve your goal.

A lot of people are screaming. I kind of get a kick out of this right now because I actually come from the networking side. We have something that was probably the hype to end all hypes, called ATM; it's amazing that it's still on the hype wagon. A couple of years ago people stopped screaming about it because they realized that it fundamentally wasn't ready; it didn't work yet in large networks. But there's a huge amount; it's almost as bad as Windows 95. It won't cure cancer, it's a nice little technology, and if it helps you achieve your goal, you should look at it. Some of the things are very... Geez, give it a rest, folks.

The goal here is to try to offer things that move, that shake and shimmy and give people a rich experience. And we're doing it; Sun's doing it; everybody's doing it. That's great. Ultimately, once again, the user is going to make their choices, and as a designer you need to decide which technology does the job for you. That's all that matters. What the name is or anything else around it, just make sure that it in fact does the job. There's some cool things going on in a lot of different areas right now.

The whole VR thing... Jim and I actually had an interesting session at another conference where we really went to see the VRML demo that SGI was putting on. And I think two or three times prior to that we wanted to get it to work and they just couldn't get it working. There's a signal right there — when you're at a show and somebody's doing a keynote and they can't get their technology to work...

But once we finally did get it to work it was actually pretty cool. Jim was very good at navigating through the little thing there and it worked out very well. If this helps you get your message around, something like this, that's great. You can actually create at some point — it's really not to the point yet where it's as easy as it needs to be — but if it helps you to get your message across to create a virtual world for the user, that's customized to them, this is neat stuff. This is one component of doing that.

Obviously, the approach of [Worlds] and other groups is to try to give you the tools to allow you to do that. That's great, because you don't want to have to go out and try and create all the stuff from scratch every time.

Once again, one of the aspects — if this is interesting to you, you should dig into VRML and understand what all the issues are and if your message will be conveyed. For example, one

of the companies I did previous work for had a lot of different business [on] UNIX, and one of them made brake assemblies. They had a real problem trying to send out the instructions for changing the brakes.

A lot of us are visual. I'm a visual person. I need to see it and draw it on the board. I can hear it and read about it all day, but until I see the pieces fit together I just don't get it. And I'm not alone; I believe there are a lot of people like that. So technology like this is very cool to try and convey a message to me and to other people on something that may be fairly complex, so I can actually offer perspective that the user can control. And they can do different things, so it's not just for creating nice little game worlds and playing the next version of *Doom*. It will do a lot more than that if your application or your goal requires that you use something like this.

Macromedia, with *Director*, they're doing some very nice stuff, too. It seems like what we're getting is a lot of different — I won't say "niche," because some people take offense — but different category technologies. And you need to select which ones work for you. I think, in general, the tool sets are something where you can bolt on a lot of these different things. As the tool sets mature more I think you're going to see more and more of an approach where the major tool vendors jump in and do a deal with Macromedia or do a deal with [Worlds] or whoever, but you don't have to go out and do the integration. Now it's still relatively difficult; it's not all incorporated into the packages for creating this stuff. It should be point and click.

Anybody designing sites with real audio today? Neat stuff, neat stuff. [NetSurf] hates this stuff, by the way — hates it. MCI's backbone just becomes completely congested; it's not a well-behaved application. But it's really neat when the user is sitting there and some sound just gets piped to them. Very cool stuff; no separate viewer. Although the viewer is still separate today, three or four months from now this stuff's all going to be integrated in. Whatever viewer you're using — browser, whatever — "integration" is the watchword here. As things mature, it all gets integrated in and away you go. So it all becomes part of whatever GUI you've selected.

But real audio is very interesting if you want to give people audio information while they're potentially reading a page, or information that changes. I know ABC News does this; the radio organizations tend to really flock to this stuff. I've got to believe that there's some other cool uses of this, potentially for things like canned presentations where you could actually click through slides and have the little description come over. There are a lot of uses for that if that meets your needs.

It would be a nice training technology, because a lot of people are using this stuff for internal use. I think I actually read where about 40% of the Web sites are for internal use only. That's a huge number, because a lot of people are still concerned with opening the door and all that fun stuff. Great technology, works like a champ; we've licensed it, everybody in the world has licensed it. So you can have them bring up and play sound and do all those fun things. Once again, if it's interesting, you should go over and take a look at it. Everybody's integrating it in their tool sets.

The biggest thing, though, is talking about this "unicast" view. Since it's really hard to do it, I won't spend a lot of time, but it's something that I believe is going to be more and more important — letting the user select what the experience is and also let you, as a content provider, learn more about the user so that you can offer them relevant content and stuff based on their interests so that they can do it safely.

The technology... As I said, a year ago everybody was worried about security. The nice thing now about security standards is there are so many to choose from. So you make your selection; they're all coming together in the tool sets, and by and large they all do slightly different things. I guess the marketers require that. Once again, I view this as kind of like HTML — I don't want to know about it, just make sure that it works, make sure that nobody grabs my

credit card and nobody understands things that they shouldn't understand from my transaction. That's all I ask.

It seems like right now — assuming that the security question is solved, and I believe there are good solid standards and draft standards and approaches and different things out there to solve it — now there seems to be this fundamental question, with me, of the user saying, “Here are my interests,” and you, the content provider, saying, “Okay, here's what I've got.” How do we bring those two things together? I can hope to get lucky and you'll find me on a “What's New” list or find me surfing — but the chances of that are becoming slimmer and slimmer as we see more content. I can hope that you'll be able to drill down with the right search tool; maybe some of them are better than others. So we're seeing a lot of work in that area because it's a fundamental problem.

Ideally, I'd like to be able to have an “intelligent agent” technology, where I can say, “Look, go find out about basketball championships from 1945 through 1950 and show them to me.” I don't want to have to go look at all these places. The user can customize and say exactly what they want and, from the content provider perspective, the tools automatically need to be able to say, “Okay, we've indexed this automatically.” You won't have to do anything. It's kind of like Web server file management; you don't have to trek their links when the system works right. When the system works right for this it automatically indexes information and it folds into an information retrieval system.

You also need to try to gather user information, and that's a real sticky situation right now. It's nice to be able to create the experience on the fly more and more, but some people take offense when you say, “Gee, we'd like to learn something about you.” Some people are more suspicious than others; they go to all the Oliver Stone movies, and they're very sure that there really is a conspiracy under every rock. That's okay, that's their right to have that view of things. As a content provider you need to make sure you offer them the choice: Do you want this service? Here's the perceived value, here's what I'm going to do. The question is whether you trust that I'm going to live up to my word or not. All content providers have to build that trust — that's another big challenge on the Web today.

You want to make sure that you provide a compelling experience first off because that also builds trust — “Gee, these people know what they're doing, there's something here of value and I may want to take a chance and actually tell them something about me so that they can customize it even more, so it will meet my needs better.” But if it doesn't meet my needs at the start, I'm probably not going to tell you anything to help you make it better because you didn't put the work in up-front. So that's pretty important, as well as remembering who I am.

Obviously, offering a compelling experience [is also important]. There are a lot of different things right now that are doing this. We can show the user things that are integrated and make the tools very “point and click” and “drag and drop,” but then the key is, okay, how do we find out profiles?

And there really is a pattern here. You search for things. You decide you like bicycles, so you enter bicycles into *Yahoo*. The only way for groups to understand what you like is by looking at those same searches; other than that you'd have to fill out a form and say, “Here's what I like.” Both approaches are valid, and probably a combination of both is the best way to get the most complete information.

And that's the problem — obviously, people are very concerned that there are profiles of them; “Big Brother is watching me,” and all that. So you clearly have to give people the option as a content provider. I know there are a lot of tracking tools for Web Servers today; make sure if you track somebody, you tell them you're tracking them because I promise you they will be very sad. Actually, very angry is a more appropriate term.

Now, I think a lot of people just don't know they're being tracked. I read about the group that tracks UseNet lists, and actually determines from people that respond to particular lists what their potential proclivities and interests might be without them knowing it. Now the company says, "Hey, you've known UseNet was public for years." Maybe, maybe.

That's a sticky issue, and I'm doing my best to just straddle that fence right down the middle. I can see both sides of it. Where the group says, "Here's a public-information asset and we've just catalogued it and applied our own intelligence to it, and our own value-added things," one could say. But did we do it with the expressed permission of all those users? Nope. Nope. So you decide where the lines sits. It is one way, though, of trying to collect this information to give the user the potential for having an experience that highlights their interests. It's a personal experience; it's this whole "market-of-one" thing.

So you, as a content provider, want to design this cool experience, and you say, "This is really neat, I know what's best for the user, I know how it should look." And the user says, "Hold it. I don't like the way you designed it — I want it to look like this." Who's right? I don't know. Clearly, there's that balance coming up and I think this is — in the industry in general — something that over the next year or so we're all going to be struggling with, because we want to design an experience that meets the corporate logo standards and all those things; but the user can throw those right out the window. So what are we going to say? There's nothing we can say. Clearly, the traditional rules where the mass market is going to take the default experience — some people will want to change it.

Think back to the way the X-Windows system worked. You could customize everything in X-Windows, every single thing. The problem is that it was so complicated only programmers did it. The majority of people who were not very technical took it at face value and said, "Okay, fine I'll use it this way, even if it's not really what I like." And the user clearly will decide; if they don't like the way that you're making them do it they'll click to something else. So you need to be aware of that.

Wrapping up, today the user really selects an access provider. They choose an interface, or maybe it came on their machine or whatever; they choose content, and they decide where they're going to spend their time, because that's the one thing everybody really values here, I believe. When they're doing this after they get over the initial hype and euphoria, they say, "Okay, I've got a limited amount of time, I am at work here, I'm supposed to put in at least a couple of good hours of work to justify my paycheck, what do I need to do the job and how much time can I afford to spend?"

You've got to capture them in that instant. That's a really big challenge, especially if you are precluded from trying to find out as much information as you can about them while you've got them. So it's trying to balance those two things. But they make that choice, so I choose a browser that was rated five cows, which is maybe my criteria, that's the most important thing I choose.

Then I go forward and tomorrow I decide I want to have this video conference. I'm not willing to pay \$200 a month to have the line installed and up all the time — I only need it for two minutes this morning. I'll pay to have the line — \$5 or whatever it costs, and there's plenty of profit in that, by the way — but I only want to pay for it while I'm using it, and you can prioritize my session based on what I'm willing to pay. You can offer a service that can rely on more infrastructure being available, not today — notice I say tomorrow — and the user selects. Please don't try this in your own home.

The user will also select the interface intelligence, how much they want the machine to try to help them or manage or control them. It all depends on your perspective. In this case, the user will decide what their perspective is. I think the industry in general will give them choices; they will offer value, and if they successfully position that value some number of people

will say, "Okay, that's helpful." Some number of people will never use this; they'll be too concerned about the privacy issue being the overriding factor.

The user is also going to select, I believe, much more of the content layout. They're going to decide if they want to see the sports section first. They're going to decide if they only want to read about hockey articles — they don't care about those damn football things. The user's going to make the choice; it's not going to be the publisher saying, "Here's what we know is important to you." It's going to be the user saying, "Just give me the whole thing — my front end is smart enough to decide what I like to see. I've told it that. I've given it permission to make the choice, and I'm going to ultimately have it my way and have a personalized experience here."

As the tools get better and you as content providers can do ever cooler things without having to work five times as hard, I think that we're going to see more of the ability to really create worlds where people decide what's appropriate to them. Personalized worlds, really, I think is where this technology is going; where, based on the interests of the user and the needs, you can create an environment that completely satisfies those needs. The way things change this may take, instead of two years, it may take three. But things are changing very quickly so I don't see it taking too long with the progress that we've made in two years.

Don't forget this, please: I've seen a bunch of sites that kind of don't know... Interestingly enough — no one was actually referring to the movie industry, I believe, though that it applies very aptly to the Web today — you can have a really cool site that's got some great stuff on it, but that's not what it is because the words are, "See Jack run." There's content there and there's an integrated message. So technology for technology's sake never works — I don't care what you're talking about. It can help if used in the right way. So I guess that's my message. With that I will turn it over to Mike.

[Tape change]

Michael Bauer: So it's tig.com, www.tig.com.

M: [inaudible]

Michael Bauer: It's T-I-G — the Internet Group — .com. All of these will be up there for you. I want to focus on the latest and greatest — and it's funny, Chris and Jim and I don't actually closely coordinate when we get together for these presentations, but it always seems that we say something that's complementary to one another when we get into this.

The one thing that I did want to follow up on — this is our site, and it's been downloaded onto this laptop here and I'm going to be using it to go through the presentation. That way you'll be able to go through the presentation when you go back on-line and see new and additional information.

The comments that Chris was making about developing this personalized one-to-one type of environment is kind of what we've been developing for a little while here. Just to illustrate this before we get into the seminar — it says, "Hello, visitor from the Internet Group. I see you're using Netscape. Since you've been here last we don't have that kind of tracking of things in place." That's kind of where we're going. What's new is our commercial Web development presentation, which will be up on the Net. Check it out and we'll take a look at it later on.

This can be a really useful type of thing. Let me illustrate what a site can do and hopefully what you'll see when you come in. For example, if you came in from another site like IBM, and were using Mosaic or something like that, when you come into our site it will try to

customize itself to your browser and to the particular company. Here it says, "Hello, visitor from International Business Machines," and if you're using *Mosaic* it pre-formats the site for you depending upon your particular browser.

That's the kind of direction, as Chris pointed out, that a lot of sites are going to, and there's a lot of value that you can get out of that — you, as in the marketing capacity. [Inaudible] the number of domains that are coming in. By looking at things from a more dynamically-created site, you start to access some more interesting things — for example, where people are coming from, what URLs are referencing them.

I apologize; this site is a little hard to see because it's a dynamically-generated graphic, but it's something that you can start to capture. I remember when I was a little kid just starting to watch *Star Trek*, I never believed that one day I'd have a laptop and a portable laser.

When you start generating things dynamically and detecting where people are coming from and what kinds of things they're doing, you can start to get a lot of interesting insights. We had just gotten a mention in Stuart Brand's article on *Hot Wired*, and in that top line you can see our hits went up with Stuart Brand's article. This is where we get hits from *Yahoo* on Microsoft Network's Home Page. A lot more hits are coming in and you can start to see those kinds of things when you're starting to get this generation on a dynamic basis. You can also start to see certain things like what kind of browsers people are using, and can configure your site appropriately.

This is actually kind of news to me; this top line here is *Netscape* and *Mosaic*, and here are a lot of the other browsers that have come into this site. We can track those. But I get flabbergasted at just the number of browsers, the different kinds of browsers that come into your site. It's just pretty amazing. That kind of information is valuable to you and you can start to capture that to create these sort of dynamic sites on the Internet, which sort of customize themselves to the particular people that are coming in and the particular places they're coming in from. So it's definitely a trend we think is going to continue.

What I'm specifically interested in is commercial Web development and going into a presentation on that. This whole site is up on the Web and you're going to be able to go to it. I'm just going to bop down through here and get these slides up on the Net.

I think one of the main things to keep in mind is this overall perspective of the Internet and how it is really valuable across the entire enterprise. This is a real serious place, and you have to try and sell things because where you're going to be successful is when you get all groups within your organization starting to use the Internet in some kind of capacity. They all are going to start to have maybe different types of benefits that are going to accrue, but they're all going to share a lot of the basic costs in terms of the connection and so on.

So when you're starting to look at a site for marketing or sales purposes and also for internal purposes, you really need to have someone at the very highest levels taking a high-level perspective on how everything is going to fit together, because that's the way you're going to get the most benefit out of it and the way you're going to be able to justify the costs for the site.

Commercial domain in general is going up. As of January, 1995 there were some 30,000 commercial domains; now there are about 115,000 commercial domains in the last count. So growth is pretty much incredible. Of course, you've got to keep in mind that a number of those commercial domains are things like *diapers.com* and *toothpaste.com*, and people that are actually registering to the marquee domain; so you have to keep that in some perspective as you're developing a business plan or business case for getting on to the Net.

But you can see the domains growing pretty rapidly up in through the 100,000 range. If we track this, giving those specific commercial number of domains and a number of Web sites that are going up — and these are the number of commercial Web sites that we think are

individually identified commercial Web sites that are essentially associated with a commercial domain — that number, this last number is a little bit too high; but that's tracking and thinking, and as more and more companies get on the Internet just about every one of them is going to start to have a commercial Web site associated with them. By this time next year [there might be] upwards of around perhaps 200,000 or more domains — commercial domains — registered and being used. And I really mean being used as commercial Web sites that are functional somewhere in that area.

But as the number of commercial Web sites grows, you have to continue to remember that a lot of people use the Internet in a lot of different ways and that, right now, there may be five million or so people — I wouldn't say 25 or 30 million people — on the Net. Those are the ones that can really just use electronic mail.

A smaller percentage of those can use actually graphic-oriented access to the Net, and those are the people that are using the Web sites. Those numbers are going to continue to grow. The graphics-oriented access is going to be the one to grow the most. But whenever you're putting up a site, you don't think just of a Web site; you've really got to think of an Internet application that's using all Internet mechanisms of communications for all these different segments.

I think a lot of people fail by really not getting their e-mail facilities down to begin with, before you put up a Web site. I don't know how many times we've gone through and put up a site and people start sending electronic mail and you have no idea how to get them to the people that actually can answer the questions in customer support. Or, God forbid, if you're trying to order products across the Internet you absolutely need to have that electronic mail connection down; you should really start there first, then build out your Web site.

It's sort of doing everything backwards. I also recommend building a Home Page as the very last thing that you ever do, as opposed to everyone working on it as the first thing. You need to do a lot of work in understanding who your markets are and what kind of information you're trying to provide, etc.

Again, another perspective on the Internet — and it's not been around very long, as everybody tends to know. Ethernet was out in 1973 and the first node was on in the late sixties; the true, modern Internet really never came on until, like, 1982; the Web not until '90; and *Mosaic* not until '92. You've got to keep that whole thing in perspective of what's happened really in just the last three or four years — from some of the very first Web sites and first commercial internet.coms coming out.

The first *Internet World Conference* was only December of '92. It's not even been two years that this conference has been going on; and we could have fit all the booths right out here at the beginning. Now you have this many people and this much activity.

The first transactions really only occurred about a year or so ago. Virtual reality just came out, the real search services have really just started to come out, digital cash is out there, *Java* and CNN on the Net... People think about concerns about security and concerns about the kinds of functionality that's out there; if you put this whole time scale up against something like the adoption of the telephone or television it's happening much, much faster and it's much more pervasive than any technology that has ever come before.

I don't know very many people who really have some kind of a handle on how much this is changing everything. We were doing this just two-and-a-half years ago and it's just hard to imagine what is happening in that short of a time frame. We call it "surfing the tsunami;" once on, you've got to really stay up on your board.

When you're going to start putting up something on the Net, you've got to think of developing a pre-publishing system. You're not really just putting up a Home Page, you're not putting up a brochure; you're adopting a complete model for publishing, as if you were going to

develop a newsletter or something like that. You really need to create this entire publishing system. We say we don't do Home Page, we install printing presses — that's the kind of difference and that's the kind of thing that you're looking at potentially taking on to really try and achieve the kind of goals that everybody keeps talking about.

It can get very expensive if you're trying to do this at a high level across the entire enterprise. You've got to go from the very beginning of creating sort of original content and graphic design to developing a set of publications. In those publications you have to reach all your different users, ideally not just the people that can use the Web and not necessarily the people that can just use *Netscape*, but everybody. [People] have all kinds of different ways and usage scenarios for the Internet, all across the different types of browsers and the graphics users and up into people that are just being able to use electronic mail.

Again, from the very beginning, setting up a mechanism to take that feedback and testing that piece out first is pretty clearly very important to at least be able to take feedback from customers, requests for information, and, of course, orders as well. It's the idea of trying to capture customer usage through customer surveys and just through monitoring your Internet, so you can develop timely content, timely updates and get them out to your users.

Overall, you're going to look at a development process that has this sort of profile associated with it. Basically, this [is the] main line you're going to go through — from design to development, then to production, maintenance, and redesign at the very end here. Each time through you're going to need a different set of inputs from a number of different key people in creating a different set of outputs.

I think the most important thing that doesn't really happen in the beginning is a very clear set of requirements for developing a site so that you have a specification of what your site is going to be really like when you go forward.

That's really the basis for developing most of your site — taking the original content, developing it and creating a prototype, doing a review, getting it out in production, getting your first version out; then having a maintenance system in place that's going to take new content and get a number of different versions that are going to be developed through rapid maintenance cycle until you're going to go through again this redesign process. And the redesign process is going to be very expensive if you don't really work at developing a very clean specification of how you're going to go about doing that at the very beginning.

If you're going to go through this process — it depends on the kind of site that you're going to be developing — but the kind of time-line that you're looking at can go anywhere from a month or so up to two or three months, depending on what kind of site you're going to go for.

So from the very beginning you're looking and planning design costs, prototyping, coordinating, and assembling content, developing some translators to get that content out of its original form and getting it up onto the Net, then generating a publication and having some evaluation period. It's going to take you a good bit of time to actually get an Internet connection, if you're going to get a substantial Internet connection — especially a high-speed connection for your corporation. Once that's in process then you've got to modify the current prototype, prepare and train people to be able to utilize it, and then roll it out and start to actually go through the maintenance and support process.

Now, what's your cost to get connected if you do decide to do that? Well, we have what we call the "six Cs" of getting connected, and those go from everywhere from the communication lines, which are the phone lines you're going to install to actually give you a connection, to the connection to the Internet, which may or not be the same thing. Sometimes you can buy Internet connection from a line from the Bell regional operating company, and buy

the connection service from another kind of company — like MCI — and role those two things together. But that's just for the start-up costs; that's barely minor just as an initial outlet.

You're going to need communications equipment to get connected to the Net; and it all just depends on how fast of a connection you're going to go with and what kind of application you're going to try to do for it. This chart shows you a lower-speed marketing channel, which maybe is a 56-kilobit-per-second marketing channel, or even maybe, internally, a human resources type of communication system that is really sort of the lowest-cost type of connection. You don't need a lot of communications equipment to get started up, not much computing equipment etc. But as you go up from T-1 to a high-speed connection where you're going to do some sales your investment conceivably goes up much more substantially.

For the communications equipment, the numbers for that can go up fairly substantially because you need to actually have something like high-speed routers and modems that are going to connect into the Net. Then the computing equipment, the PCs that you're going to use to get connected to the Internet — there's going to be three or four of those that might be involved in a high-speed connection to the Net.

[You also have to take into account the cost of] software that you might want to acquire in terms of databases if you're going to do a sales system, or the commercial Web servers associated with them. And [there may be] some consulting fees to get totally connected to the Internet. To get your initial system established you're going to find some value in having some help getting started up.

Now, those are just sort of the start-up costs. Once you get fully connected to the Internet you're going to have on-line costs and ongoing annual costs. Those are going to differ depending, again, upon your speed of connection, and your costs of getting a connection are going to continue to go up. You're not going to have to buy as much communications or computing equipment, but you may need to allocate some more for connection software upgrades; you may need to allocate more for developing and maintaining the site, especially if you're going to do external redesign on a regular basis. So you're going to see potentially that kind of a profile for getting fully connected to the Internet on an annual basis.

Finally, if you're looking at overall, what your total first-year costs are going to be, you can see they're going to lay out sort of like this. Your annual costs — depending upon your speed of connection versus your start-up costs — you're going to be seeing potentially a pretty significant investment for a very high-speed sales system. Now, getting that kind of investment in there with really all those numbers in place can become a very hard sell to your corporation to develop a full sales channel that is basically utilizing the Internet.

So it's not a Holy Grail; it's not the ultimate answer. It's a significant investment. Again, going back to your business case, if you have a connection one of the nice things is that you get economies that scale well. Everybody can start using the connection; not just sales but marketing, customer support, and internal operations — they can all start to utilize that connection. So your costs can be spread out pretty substantially. Having that kind of business case can make more sense rather than something that's just specifically dedicated to one particular organization.

If you've gotten a connection, once you've gotten it, what's it going to look like? What's going to be involved in developing and maintaining that site? This is a diagram that's set up to sort of illustrate the overall configuration of what you've got to deal with within the development — all the way from design through the development, through the maintenance to the production and redesign cycle.

Typically, there's someone who's always been identified as a "Webmaster" in your organization. Now, that can work for a small organization or an upstart, but you cannot have one single person who's going to be in charge of providing all the content onto a site. You're

going to have a number of different people that are going to be contributors, and they're going to be providing that kind of content to the site — some people that are going to be just textual content [and some just] graphic content.

They're all going to need different tools to be able to pass through a Webmaster — someone who's going to coordinate and make sure the policies are followed, make sure that someone is reviewing the content before it's going up so that it's appropriate.

Then you're going to have a site that you've got to be able to establish for development purposes, some place that you're going to be able to provide the content stage to test it out before you actually role it out to production. Your various users start to use it; maybe from different kind of companies that may be out in the field and maybe in different countries.

Underlying all that, there's going to be some [a group of people who act as the] developer — if you're going to be developing a larger system — who's going to be in charge of sort of just creating a set of tools or strips that you may need, or being able to utilize the new tools that are coming out to help you create more dynamic interactive type of services on the Net. Those people all need to be coordinated in some fashion with one another, but they're going to be instrumental in providing support on the development side and on the production side.

If you're looking at a large-scale system, you're going to have some kind of a database system that's going to be in there. Then someone's going to have to administer that database, and also the production server as well, to make sure that the database and the servers are actually up and running and functioning very well.

So these costs — again, these are more of the soft costs that weren't in the specific hard costs that we talked about earlier. You've got to have this whole environment in place to really be able to provide content and get it up onto the Internet, and do so in a fairly reasonable fashion.

Now, there's this architecture that we use to manage an environment, and it's helpful for us and may be helpful for some of you as well. As you're starting to create these kinds of sites you need to... Looking at the entire site, you have your production servers and your development servers, where you're going to have at the baseline — these are the servers down here, these are the authoring tools, the contributors are on this side, and these are the users on this side, what you're going to be layering on top of the computer and layering on top of your different Web servers, which are going to be used in both production mode and potentially on a development mode.

For the contributors, laying on top of them is going to be a set of authoring tools, which could be any mix of a different kind graphic-authoring tools. The browser is going to sit on top of the user's computer. Over on the different servers, you're going to have potentially a number of applications, scripts that are going to be established and that work on top with the Web server to provide the kind of functionality and value that you want to be able to provide to the user.

So from the production side you may have feedback forms or customized scripts to access databases. They're using different kinds of database interfaces that may come with the Web server or that you may write yourself to access information that's from your legacy databases.

At this front end out here, you may need to put a layer on top of your Web servers or take advantage of some of the new Web servers that are coming out that have the ability to dynamically generate information — like I shared at the beginning [in terms of] what we've done — but also have this ability to start to manage different sessions for a user, so that you can identify a single user that comes into your site, identify them on a short-term basis or on a long-term basis. If you're identifying them on a short-term basis, there's a lot of value in being

able to manage that particular session. You can trap them as they go through it, you can see where they're going and what they're doing and you can utilize that technology to provide additional value.

For example, on a sales application it's necessary to provide a shopping cart for them to go through a site, to grab a number of different products from your site and add them to [their] own personal list.

If you want to start to create what I think are going to be the up-and-coming types of customized Home Pages that are actually created for a user for a particular site... When someone comes in, they log back in and connect to their site again and they want to be able to know where they've been, seen what they've done, and have their own — as Chris pointed out earlier — menu items that are from that particular site. That's another value of having some kind of a capability that manages a session for a user, and actually starts to remember a user on a regular basis.

M: [inaudible]

Michael Bauer: Yes, most of this is stored on the server side, although there are lots of different technologies that are starting to work together between the server and the browser. Some of the way this works — someone asked me a little bit earlier about this. When a browser particularly connects to a server it may connect in a couple of different ways and identify itself to the server: it can identify itself either by the specific reference or the URL that they're coming back with; or some of the browsers have what are called ["cookies"] that are established with a particular server, where the browser essentially has an identification that's been assigned to it from that server.

And I suggest you get your [cookies] fast because they're going quickly. There's only a limited amount of these [cookies] per browser and they're permanently stored in your browser. It's like the battle for domain — there's going to be a battle for [cookies] within browsers, and that means that there are only so many different unique identifiers that browsers can have. So if you, as a company, want to start being able to create this capability to track and be able to at the very least track when someone else comes back to your site, you want to be able to assign them a [cookie]. There's only 300 slots out there and, with the domain end-growth, you might want to grab one of those [cookies] more quickly.

That's probably going to change long-term, but, again, the whole point is that there's a lot of coordination that goes on between a browser and a server to be able to go beyond just the ignorant Web servers that are just providing pages when anybody asks for them and to start to create that dialogue between a user for a lot of different purposes. So that front end has to be established.

At the back end you need to have some kind of a development environment in place that's going to be able to provide a lot of staging and lot of content and a lot of control. This is a great place where you can start to use the Web both for internal applications — the development server may be a good place to actually have your human resource services established — and you can start to take advantage of what you might be doing out here in production servers.

There are tools and technology that you're utilizing there to actually use them back on the development server, and really start to use this tool as a project management system so that you can coordinate between a number of different people that are maybe all starting to contribute content to the environment. It's a great tool to start to use that.

These two servers are really what you should focus on developing, as both the outside production server for the inside development server and the development server used for both

external purposes — for staging your content for publishing — and your internal server for use in developing human resources. And some mechanisms to be able to start to manage how a number of different contributors are all starting to provide content in a coordinated fashion.

I think that's a fairly reasonable architecture on what you've got to prepare yourself for as you're developing these large-scale systems; we will enlarge number of groups within a company that are trying to be able to use the Internet for external purposes, and the Internet technology for internal purposes as well.

Any questions about that kind of architecture — what kinds of things are involved with the cost associated with that?

M: [inaudible]

Michael Bauer: It depends on your security concerns, for the most part. Now, this doesn't have the actual network layer, but there may be — in between this production server and the development server — a firewall sitting right here. And on that firewall that's a third computer. So if you're talking about large-scale types of systems, you're really talking about at least three different computers that are going to be involved in managing the site: one for your production server; one for your development server; and one of the gateway servers that acts as sort of a gateway between people coming in and keeping people out at the firewall, and keeping them on the inside going out and using the Internet for internal purposes.

M: [inaudible]

Michael Bauer: It can be one if you just don't want — typically, the security consultants, say, get your production stuff off of your firewall. You don't want anything on that. If you're going to use a firewall, if you believe that firewall technologies are appropriate to your risk profile, then firewalls are usually set up as scheming down. No one else has log-in accounts or those types of things; no other applications are really running that are absolutely necessary. Your development server sits inside the firewall and the production server is on the outside.

You can do this with one box — *Apache* is a great server — so that you can have a lot of different Web servers running off of one box. It's a pretty fast machine.

Any other questions about the business case or the cost in values, or overall development environment of your process that you're going to go through — timelines to be able to create a site, issues associated with it?

I'm going to go into a few things about design, just to give you some philosophy about what we think the overall design process is all about. We think you've got to look at these things — sort of a “force field” processes. When you design a site everybody focuses on Home Page design, and that's like focusing on the executive report or the cover of a page. You really should do that last. The graphic designs should follow really solid information, and that means how do you actually organize the site to determine who your market happens to be.

There's this great book called *Information and Guide*. Anybody heard of this one? It's a book by a gentleman who did San Francisco's *Yellow Pages*. He says there's an infinity of infinities of information that's out there of knowledge or data, but basically there's only five ways of organizing that information: by subject, by chronological order, by alphabetical order, by subject, or by statistical [means] comparing data to one another. And there are five different ways of organizing information such that if you utilize those principles you can start organizing your information more clearly.

Once you've organized your information more clearly, that starts to speak to what kind of graphic design you want. Principles of not going too deep into a site, being able to get to the

things you need quickly — those are the things that we're going to go into that impact your graphic designing. You really should start there because going through too many graphic design cycles is extremely expensive. You bring in a graphic design artist and you want to try something and see what it looks like; you don't like it and you can do it again. If you don't really have a clear understanding of the information design first, you're going to waste a lot of money doing your graphic design.

Graphic design is not just a Home Page — it's the Home Page and all the subject headers that you go all the way around through a site and all the navigation icons that you're going to use. All that needs to hang together and it all needs to go along with your corporate identity, so that whole bulk of work that you need to do you should really do last, after you figure out what information you want and how you want to organize it.

This interaction design is really the heart and soul of a site. You're trying to develop this publishing system — how do you interact with your users? I really think that this is the most difficult part of the design — how do you structure a dialogue with someone? You're basically almost, in some ways, writing a play or something. You need to be able to structure to actually run several plays where the players can go unlock the different directions.

Your [idea of] what different kinds of interactions are going to go on in your site will enable you to establish the different kind of dialogue that you're going to need. Again, that's going to impact the information of the design and then the graphic design, so you really need to think this through, on a higher level, of who you're trying to get to and what kind of a relationship you're trying to establish with them before you get to actually developing the graphic design.

This lower, sort of “censorial” design is what you're looking to do. How do you want this thing to be perceived? What kind of sense do you want to give to people when they come into this site? That's where the last kind of thing impacts back on what the graphic designer's doing. What kind of corporate design — do you want a staid corporate site? What are you trying to look for? And that has impact on the kind of color designs — colors that you pick and graphics that you use — and even the graphic designer that you pick.

Get a good design, then you can go through the development process and then you can look at actually creating the kinds of things that you need to create. But the focus should be entirely on adding value. Again, this is probably... Has everybody been to the FedEx site here so far? This is an example of what probably is one of the best designs up on the Internet. The FedEx manager says they constantly laugh at how many people really like their site. They did it kind of quickly and it doesn't have really wild “WYSIWYG” kind of graphics associated with it, but the difference is that it actually adds specific value. You can specify a packaging tracking number and you'll actually find specifically where your package went.

That's this theme of Chris's — I'm trying to get to that, actually — the one-to-one interaction that you need to be able to establish a relationship with a specific person. That's when the value of the Internet starts to come out, and the value of the Internet comes out in relationship to other channels.

I can do this kind of thing, get more information directly off the Net, not wait for 1-800 service or anything along those lines. That's where this service starts to add in unique value that you can't get through any other communications channel with your customers.

That's the ultimate thing that you need to really understand — how this introduction of this new channel differs, compares, and contrasts with the other channels and whether or not it complements them. In FedEx's case it complemented, so it makes good sense. They're going to continue to extend it. Now, once you've defined the value of your site and really understood the design of it then you may look at some of the graphic design capability, the graphic look and feel of your site.

This is a great site that has captured some of that kind of thing. Who's been to the Southwest Airlines site and seen it? It's good. It's potentially becoming a dated type of design — the designs probably become dated every three months on the Net. This design uses a metaphorical navigation device where there's about 14 different things it can connect to. It's kind of for people that are visually oriented, and if they are they'll be able to kind of get it right away — “Oh, I'm at a ticket counter, I can do lots of things. Maybe if I click on this guy I'll get a message, and if I click on this mail thing I can send an electronic mail message. If I click on the cash register I can find out prices. I can click here and find out service areas, news, fun vacations, information about reservations, not exactly making reservations quite yet, but I can do that kind of thing and then also getting at the picture gallery of the planes that the site provides.”

So they thought through, I think, pretty clearly what kinds of things they wanted to be able to do. Maybe they got lucky because they only have one sort of point of experience with their customers, so they could utilize this graphic to provide a navigation for their site; but this type of approach is pretty helpful. A lot of designs are going with smaller graphics. If you look at *Java*, they use small icons that are very specifically focused. We think that lighter type of design is helping people understand what kind of information they can get to and what kinds of interaction they can support, or where the designs are going to go, but this is a useful metaphor to keep in mind.

Again, this sort of gets back to this whole interaction. I talked about developing a publishing application, and a lot of people are starting to come up with a different type of metaphor — a programming metaphor, actually programming a small [application that's] something like a television station.

Something like “The Spot,” which is a daily sort of Internet sitcom where you can go to every day. These are all struggling actors — they're not struggling right now, I'm sure Fox has picked them up and they're going to do some kind of a television series — but each of these actors has a house in Manhattan Beach, California, and every day they were just basically jabbering on the Net. People kind of tuned in to them and kept coming back to them on a regular basis. It got so it was a “Cool Site of the Year” by whatever self-appointed Internet God that decides what goes on and the different types of capabilities that are associated with it.

Chris talked about how almost every site now is updated at least monthly. That's why I say I want to write a book like *How I Hate the Internet*, because you're obligated potentially to do this kind of thing. It doesn't make any sense to do this if you're not going to do this; so if you're going to make the investment you've got to make the investment both in all the equipment and capital costs and also in internal costs, and not only for development and designing the site to begin it, which is nothing compared to what you've got to do to maintain and continue to keep it updated.

That's the real cost. You need to understand — again, going back to the first principle and looking at the entire business case — what you're going to do with the site and does it make sense for your entire organization.

Now, if it does, there are a lot of different ways to sort of get your name out there. This is actually a screen from *Submit It*, which is a site that you can use to submit a single URL to this site. It will go out to all the other search services that are out there and it really provides you with the capability of advertising your site. This is particularly useful for you guys when you want to be able to market your site quickly and make sure your sites out there have a capability to go from one spot in *Yahoo* and *WebCrawler* and all the other sort of categories. That's pretty useful.

Part of the overall process of free marketing is only going to get you so far. You really want to start on getting a site out; you're going to want to really start looking at advertising.

More and more content comes up and it's more and more difficult to find people. Advertising is going to get more and more expensive on these more popular sites. That's definitely going to be something you've got to go to.

Bottom line — always coming back to the business case. Does it make sense? Can you get enough benefits from each of these different areas while still sharing a lot of costs, which can be significant in terms of equipment and also in terms of commitment?

Lots of tools are coming out to make it easier and easier to do these kinds of things, and I think it's definitely in your interest — if you're on a surfboard and taught not to look at the board but look at the shore — where are things going? I think things are going more and more away from static white pages and static servers to dynamic servers that are providing you with access and customers with access that's dynamically presented and generated for them; but also providing the ability for you to go in and actually start to make changes yourself and manage a site more quickly.

Our whole site-wall is dynamically generated and we're able to go in and make modifications to individual page elements — or “objects,” as we call them — and groups of objects in a straightforward fashion. That lets us change and move things around and modify the design and so on. There are lots of different tools that are coming out to do those kinds of things, and as you're starting to scale up and have a large system where you have a lot of people involved with that, those are the kinds of things you kind of need to start to embrace and look forward to.

That's pretty much my piece of this. I'm the dry guy, I guess. I just try to provide the basics. Jim will be coming in and talking a lot more about marketing great sites and things to do, and contests and so on. I think later on we'll talk about where we think things are going in terms of intelligent agents and their integration with the dynamic animation capabilities from *Java* and so forth. Any questions about anything?

[Tape change]

Jim Sterne: Chris was kind enough to introduce me this morning, so I won't belabor the point. I'm an Internet marketing consultant. I've been in sales and marketing for 15 years, and I'll provide a shameless plug for my new book that's available in the John Wiley booth. I won't let you forget that one. Chris was kind enough to say that I was going to present “Sterne's Rules of Server Design,” and when he told me he was going to do that I wasn't sure if he would. These are the marketing rules here in a nutshell: Make your Web site fun, useful or interesting; make it easy, fresh, targeted; [make it] a two-way street; and make it personal.

Those of you who wanted to catch other sessions, now you know everything. If you want to know what I mean by that, there has to be a reason for somebody to come to your Web site, there has to be something to draw them there. And if making it fun or useful or interesting is going to get them to show up... If you're really good at it you'll be listed in Glen Davis' “Cool Site of the Day.” You might show up on the “What's New” pages. But the best of all is word of mouth; that would be fabulous. If you have something that's really worthy for your constituents, the people that you're targeting, then people will talk about it.

So how do you make it fun and how do you make sure that you're keeping with the culture? We hear a lot about “netiquette” and Internet culture, and I think it's important to know a little bit about the culture so you understand why the Internet rules apply. If you understand why, then you don't have to go by any hard-and-fast rules — you can just use your common sense.

The Internet is a frontier culture. That means that when it started it was a small group of people in uncharted territory. They all had the same goals, they all had the same problems,

and they were all working together remotely. So if somebody said, "This is hard to get files from this machine to this other machine, does anybody have a clue on how I can do that?" And somebody else said, "Oh, here's this file transfer protocol thing, why don't you try it?" And somebody else said, "Oh I did try it but I fixed it a little bit and now it's a little bit better."

So it was this idea of "let's work together and make this community." Sort of like if somebody's barn burned down, you'd get together over the weekend and help him raise it — again, because their livelihood supports the community. You want everybody to be able to work together, and it was very personal, there was a code of honor, and it created the gift culture. The gift culture begins with the fact that the Internet works by agreement, not by contract.

I put my computer on the Internet and suddenly I'm saying, "you can use my computer; if you want to send e-mail to him you can route your packets through my machine." I'm making a gift of my machine to the network, supplying a resource. The next step was, "Gee, I've got a database of weather statistics for the last 20 years, I'll make that available on the Internet." It's a gift.

Now, it's that frontier mentality and gift culture you've got to combine in your marketing approach — because it's expected, because it's tradition, but also because it's how you compete for people's attention. There are so many Web sites to go look at; why would they go look at yours? Because you offer something of value, something that's interesting, something that's fun. Fun is hard. Comedy is not pretty. Making something that people like to go to is real tough because the most successful ones are non-commercial.

One of the most often visited sites is the "Cool Site of the Day" site. Let's go there and see what Glen has discovered. Glen tells me he can take sometimes up to five hours of surfing to find something. He says it's kind of a combination; first of all, there's so much [of the] dregs out there; and secondly, he's seen a lot of sites so he's got to find something new. It takes him some time, which saves us time, so therefore it's a very popular site.

How does a commercial entity make it fun? Or, if you're doing an internal server, how do you get people to go read the employee manual? Why would you want to go read that? If I specifically need to know what the travel policy is, okay, I'll look it up, but I won't look it up again. It's a challenge.

Here is something that's fun. This is called "Riddler." Riddler is one of those fun things that's out there that's a game, and you can win prizes. As a commercial company, you can sign on with Riddler to become one of the sites that somebody has to go to in order to play the game. So you pay for the privilege, and a user gets to just go and play the game and have a good time and maybe learn something about your product along the way. It's an interesting idea.

But if you have a product like allergy relief medicine, how do you make that fun? In fact, as most of these slides — I didn't click these just before starting today, so they're old. This one has actually been updated. The FDA came down on them and said, "No, no, no, you have to call this the [Clairitin] Allergy Symptom Relief site." So don't forget your attorneys — you have to keep them involved in the process, too.

How do you make this fun? Clearly, if there's a coupon at the bottom that's kind of useful, that's nice. But what do you do to make it fun and get people to show up? These folks decided to provide the "Sneeze Page" — yes, you can now download disgusting sound bytes of different people sneezing.

I give straight A's to these people. [Cognos] makes database and data-analysis tools. Pretty dry, pretty boring. Well, they decided to tie in the World Series; what they're offering is their power-play piece of software and 1995 regular season statistics and 1995 postseason statistic databases which you can download with a small version of their product. You can slice and dice baseball scores and stats and batting averages as long as you want. Oh, by the way,

you're using a trial copy of their business tool — they hooked you. It's free, come and get it, right off the Home Page.

[That's a] marvelous tie-in of a cultural event, and something that's fun, something that thousands of people are downloading that has nothing to do with anything that would ever make anyone want to buy their product. But probably enough people in information systems departments are interested in the World Series who would say, "Gee, this tool is easy to use," or "Now I know enough about it, maybe I'll learn about their professional version of it and I'll go talk to their sales reps." That's a nice way to draw people in.

Then, of course, there is just good writing and good Web design. Who here hasn't been to the Ragu site? Okay, about half of you, great. For the rest of you, it's at www.eat.com. This is "Mama's Cucina." If you have a crust of good honest bread and a nice glass of wine and a little pasta, you are a rich person. But it is a warm and friendly Web site. It has a style, it is Mama talking to you. All the way down to the bottom of the page it says, "This next part was written by Mama's niece Anna the lawyer," and it's the copyright clause.

It's friendly and fun. This little welcome comment changes every time you show up. Hit reload and she says, "Please come in my kitchen, just remember to wipe your feet." You can learn to speak Italian; Professor Antonio — "When the moon hits your eye like a big pizza pie, that's amoré" — you click on that and you can hear it.

But they didn't stop with just that. You get phrases like, "Next to Ragu pizza sauce I love you best of anything else on earth." That's an important phrase to know in Italian. So this is fun and friendly. They also have Italian art lessons, and they also have goodies from Mama. So here is a coupon — not that you download it, not that you print out — but you send them e-mail saying, "Yes, I want that coupon." And they mail it to you physically, for two reasons. One is they can really track it individually now — when that thing comes back through the retail system they know where that coupon came from, and you can print up dozens and dozens of them and it doesn't confuse the retailer.

Imagine you're a checkout clerk and someone walks in with a laser printed piece of paper with a coupon on it; you're going to wonder what magazine they got that out of. So this is a nice easy solution to that, and it tracks it. But the Ragu "Internet Surfing Team T-shirt" I think is even better. Here are the steps you have to go through: send them an e-mail that says you're interested in the T-shirt; they bounce you back an e-mail that is a form for you to fill out — name, address, and a couple of questions; and you send that form back to them in an envelope with \$3 for shipping and handling and two proof-of-purchase coupons from the back of their jars.

Oh, they made you go to the store. They made you buy the product. How many people are doing that? Ragu is back-ordered, and they can't keep enough of these in stock. People like the site — it's a friendly place to hang out, they enjoy it, and they're willing to participate.

Fun is hard. Useful and interesting actually isn't as difficult because you know things about your industry that are not trade secrets, but your company is a repository of knowledge about that industry. It has to be in order to compete. So there's some information there that's worthy of publishing for people.

Well, here's some information that's worthy of publishing. Everybody's heard of the FedEx site because it's so easy to comprehend. You type in your air-bill number and it tells you where your package was, when it was delivered, and who signed for it. Marvelous. Customer service — really nice, clean and crisp, useful. And yes, I do all of my stuff FedEx now instead of UPS because I was able to do this. And yes, UPS now has come on with their competing version; in fact, they even have a time calculator where you put in the distance and it says approximately how long it will take, and you put in the weight and it will say how much it will cost. But, gee, I'm used to FedEx now. They were first, therefore I'm their customer now.

Here's Alamo Rent a Car: www.freeways.com. You can rent your car, you can check out the map, you can download a bunch of games to play with your kids who are in the back seat because we're not there yet. But you can check the reservations, look at the locations of where you can pick up cars, check out the car models and see if it's big enough to hold my golf clubs. Am I going to get all six kids in the back seat of that car? [You can] tell them when and where you're going to pick up and drop off, check for availability quick, and make your reservation.

Now, this has been up for a couple of months. The announcements we're hearing at this show are that credit card transactions have been approved, security is getting tighter, and electronic cash has started to happen. There are now banks that are on the Internet, so by this time in six months the actual money thing will be a dead issue, and we will be buying and selling with no hesitation whatsoever. But offering this kind of information to people... Is the car that I want available in the city and on the date I want? Okay, make the reservation. That's useful, that's something I'm going to go to because it will actually make my life easier.

Here's an interesting example. This is the General Ribbon Corporation, and they refill ink cartridges for ink-jet printers and toner cartridges for laser printers. There's nothing very interesting, fun or exciting about that; it's just a supply that you have to buy every now and then. They said, "We want a Web site, we want to be up on the Web, it's hip and cool, let's put up a Home Page." We went around and around about why anybody would come there. "Oh, well, our products are less expensive, they're environmentally safe, they're high quality." Yes, but why would anybody want to go there?

And we finally found out that they have a special knowledge: they created the guide to ribbons and cartridges. You pick if it's laser, ink jet, dot matrix; in my case, I have an Apple *StyleWriter* and when it runs out of ink and I go down to my local Staples and I think, "Oh, I'm about to run out of ink so I better pick up another cartridge, but I don't know what the part number is." And I look and there's these little boxes and there's hundreds of them and one of them fits my printer. So I can go to this to find the part number I need, and now I can even call Staples and order it or I can go down there.

But they add, "By the way, consider the following alternative, which is money-saving: specially formulated ink, environmentally sound, shipped to you directly." So they're giving you the benefit of their information, of their knowledge, and they're serving you something that's of value to you and then giving you the sales pitch. That's the correct order.

Well, what is interesting or useful about allergy medicine? It will make me feel better when I'm ill. And the Sneeze Page is funny — I'll show up there once and laugh at it and tell my friends that I found the Sneeze Page, but I'm never going to go back there. Why would I go back here? Because they offer gardening for allergy sufferers — when to plant certain plants, which plants are going to be nicer to your condition, low-pollen plants by zone, and all kinds of gardening tips and advice from people who can come in and give you what their experiences were. [They're] creating a little center of, "We're people who have common allergy problems."

I know a woman who recently took a six-month sabbatical because her son has really serious allergy problems. They had to redo their house when they found out what the problems were to make sure that the carpet wasn't emitting fumes, make sure that the paint was right, [check] what he eats... She says that she has met people through this gardening advice whose children have the same condition, and a support group has formed out of it. That's useful; that's something people will come back to, and, of course, they'll remember the product.

So that's fun, useful, or interesting. Now we have to make it easy. And that falls into a couple of categories: find, read, navigate. If you can't find it, what's the point? If you can't read it, what's the point? If you get lost when you get there, you've wasted your time.

You have to promote a Web site — if you have an 800 number and you don't tell anybody, nobody will call. If you have a Web site and you don't announce it, nobody will call. So the first thing we want to do is get out there on the Internet and tell people that you have this new Web site.

There's some help you can get. These guys — *The Postmaster* and *Submit It* — are two services where you type in your URL, you type in your description and you hit "go", and it goes to all of the What's New and Announcements and Web sites and posts it for you automatically. Pretty swift, pretty nifty.

But I prefer the Eric Ward method. Eric Ward is a young man who started *NetPost*. He will be a publicist for you; he will go to each individual announcement Web site and look at the normal length, will look at the style, the tenor of the posts, and create the right post for that particular site.

In a lot of these sites the stuff automatically comes in and then human beings look at it and say, okay, it belongs in this category, or that's not interesting enough. Eric Ward knows the players — the people behind all the Web sites — and walks you through the process. He is an Internet publicist, somebody who's worthwhile to work with.

Make it easy to read. It's real tempting, when you create a Web site, because it's a new medium to say, "Let's trick it up, let's make it fun, let's change our logo a little bit, change our corporate style a little bit." Well, gee, we just lost brand equity, and we've made it harder for people to read.

Everybody likes to pick on *Wired* magazine, and, yes, I admit to being over 40 years old. This is nicely designed; there's not too many choices, it's pretty crisp. I have trouble with the background color and I have no idea what those icons mean, but it's targeted to a specific audience, so if I were a generation X-er I'd look at this and I might be impressed and might be delighted and happy. And that makes sense, but there is no sense for hyper-fuzzy.

This deserved being the Netscape Hall of Shame number one pick. It's not that you can't read it, it's that you don't want to. I had no interest in going any further in this Web site to find out who they are or why they are. It just made me feel bad.

Make it easy to find, make it easy to read, and then make it easy to navigate.

If I give you my business card and it has a street address, you have innate tools that you grew up with — you know that I can find a city on a map of California, I can follow the freeway system, I can get off at an exit, I can turn right and left at a stoplight, and when I get to the building I know there's visitor parking, there's a front door and there's a receptionist who I can announce myself to.

Also on my business card is www.targeting.com, and when you go there you don't know — there's no general rules, there's not even gravity. Where do I click and why? It's your job to help your people figure out how to get into your Web site and what can be expected there.

Here's an example of someone who did a pretty good job. This is the usual suspects up front — Overview of News, Products, Contacts, Service and Support. If I click on Products, that menu jumps to the top of the screen and products is pushed in. Okay, I know where I am, and if that's not where I wanted to be, instead of going back to the Home Page I can move sideways because those other choices are still up there.

Now, if I go into Peripherals — let's say Jim is looking to buy a new printer because his *StyleWriter* keeps running out of ink. We go into peripherals — and there are a bunch of them — and sure enough, I can find printers and click on that, and here's a humongous list of the printers that HP makes. Well, I don't know from printer part numbers and names — they're not very descriptive names, they're computer part numbers.

So if I'm a technician looking for a particular part, maybe that's useful. If I'm just trying to buy a printer, it doesn't help me. There's something down here, a little index box. Let's go to

the index. The table of contents lists everything that's on their Web site — this goes on and on and down through the floor. It's a big list.

If you're looking for something in particular that you know you're after, it's a great resource. If you're just kind of shopping for a printer... Let's try Search. At the top there's always these binoculars, and you can click on that and go to the Search page. Well, there are some instructions with this search page; in fact, there are three pages of instructions for this Search page. There is Context Search, there is Boolean Search, there's Fuzzy Search, there's Text Search, there are two databases to search from and there's help with keywords. You need to be a computer scientist to figure out this search tool.

On the other hand, HP sells a lot of equipment to computer scientists who would love to come in here and learn how to powerfully find what they want. They're interested in that and they're capable, so for them it's a good thing. For me, I'm still trying to find my printer.

Well, let's go back to this Peripherals directory and discover "Helping You Choose." Okay, I definitely need help — what is that? Well, here are some questions for you. What kind of computers will you be primarily connected to? Oh, Macintosh. Black and white or color? Black and white and color as well, rather than just black and white. How many people will share the printer? Just a single user. I know the answers to these, and they bother to ask you. If I click on "Find Printer," I get a list of a handful — nothing overwhelming — the platform-supported, what style and type they are, and some pricing information. I can say, given this price range, that I'm interested in that one and, bingo, it's found the printer for me.

Now, if I'm a technician looking for a part or if I'm a purchase agent looking for a specific printer that's on the requisition, if I'm a computer scientist looking for some obscure thing somewhere in the HP database, or if I'm a guy who wants to buy a printer, I have a way of getting into the HP Web site. They've provided enough tools for me to access thousands of pages. That's good navigation.

Keeping it fresh [is important]. People expect it to be fresh. Those of you who have ever printed brochures with part numbers and prices know that within about 10 minutes somebody changes something; product management changes a price, somebody in the technical department changes a feature, and sure enough your brochure is — well, it's only a little out of date, there's only a couple of things wrong, and I'm not going to spend another umpteen thousand dollars to reprint it; we're going to have to wait until it's really wrong before we get that far, or we'll get those little stickers and hire some high school students to stick them on 10,000 times. You've done that before.

On a Web site I expect it to be current because if you change something it only takes "that long" to make it correct on the Web site, and now it's published globally. So as a customer I expect that to be the latest and greatest information. Now my catalogue can say, "For the most up-to-date information visit us at www.company.com." So make sure that it's fresh.

One of the problems that you're going to face is that a brochure is a physical entity. It sits on your desk, you look at it and you know when it's out of date. A Web site is kind of a mystery; it lives on the computer and you don't look at it all of the time. You don't see it, it's not in your face, how do you remember to update it? If you've got 10 pages on your Web site you can keep track of it; if you've got 20, now you can do it on a napkin; but if you have hundreds or thousands of pages, like most companies do, it's very difficult to keep track.

Keep a calendar. In fact, I've seen companies that put expiration dates in their Web Pages under "Comments." You don't see them in the browser. So they can run a report that says, "Show me everything that's going to expire next week, and they can call up the department manager and say, "Hey, you owe us new pages as of next week. And if you don't

give us new pages, we're pulling the old ones off." It's your responsibility to make sure it stays fresh and to set up systems to help you do that.

Finally, people expect it to be the latest news. I'm constantly surprised by going to companies and seeing that the latest press release is four months old, or the What's New button is from 1994. Chris mentioned that earlier; that's unacceptable. I've been beaned really bad for that. I came back from one seminar saying that to people, and I got an e-mail that said, "Really enjoyed the seminar. Visited your Web site — information was really old. Thanks for the lesson." So I wrote back in e-mail — no, I went and updated my Web site — and then I wrote him in e-mail, "Very sorry, thanks for the lesson." Sometime tonight I will change where I have my list of speaking engagements, and I will make this one under "Previous."

M: [inaudible]

Jim Sterne: I suggest Level One and Level One-and-a-Half to get into your Web site. Level One is the Home Page. It's the image and access front door, and it's the place where people who are just surfing can kind of get to know you and check it out a little bit. But somewhere right there on the Home Page is the Expert button, or the Search button, or the "I know where I'm going, just let me get there" button, because the second time somebody comes to your site they're not surfing, they're there to get something in particular. The first time, yeah, they want to see what's cool, what swivels and twists and what kind of music downloads they can have and all that stuff. The second time they're there to do business, so you want to make sure that there are more tools for the guy who's looking specifically for something because he's more likely a buyer than a surfer.

Don't do this in a vacuum. Make sure that your Web site is tied in with the rest of your marketing. Maintain your brand equity, make sure the logos look the same and that the company attitude and style is the same so that it's recognizable. And tie it in with all of your other events; let people know where you can be seen in public and what trade shows you're going to be at, and what specials you're offering and what discounts are available. If you're working with a dealership organization or some sort of distribution organization, direct people to whatever events they're up to that are promoting your products, etc. Keep it up to date.

Silicon Graphics — they're out there a lot on the Internet. They like to seed their logo all over: "Powered by Silicon Graphics." They're pretty good at keeping their Web page updated. You go there and, periodically — not quite every month and it's not every two months — they come up with a new Home Page. That's nice. They keep the same button, so that if you go there and it looks different you still know how to navigate if you're looking for something in particular. But there's always something new and something interesting for just the general browser to look at. So that's keeping it fresh.

Now we want to make it targeted, and for that I need to go to the next file that I've got. Another reason that you should keep your graphics small is that all over the country there are people like me who are using PowerPoint presentations to give examples of Web sites, and if your graphics are too big and it takes up too much room, PowerPoint can't show one 20-megabyte program to split it into two 10-megabyte programs, so we're going to call up the next one and talk about targeting.

The first question that I always ask people who are working on their strategy for their site is, why on earth do you want one? Well, it's hip, it's cool, it's the right thing to do. No, no, no. What are you trying to accomplish, who is it for, why are you creating it? That gives them pause.

Once we've figured out what the reason is and what the purpose is then you can start worrying about design. Are you trying to improve your corporate image? You've got another

ten minutes to do it. If you don't have a Web site yet — six months ago it was nifty and cool to have a Web site, twelve months ago it was newsworthy — Bank of America, the first bank on the Internet. Well, all it was was a two-page brochure, but they were the first one. Now it's kind of iffy. Six months from now you will be conspicuous by your absence. Even if it's a bad Web site, get it up there — it's expected.

Customer service is my favorite soapbox. If you want to use the Web for customer service, I'm delighted. Just to let people know that your product is still out there and doing well and top of the mark, for prospect qualification, to help the salespeople move through — if you've got a long sales cycle, if you've got a complicated product, your salespeople spend a lot of time giving presentations and giving seminars, trying to educate people about what your products are. This is going to let [the consumer] learn it by themselves, and they're going to come to your salespeople knowledgeable and ready to ask buying and closing questions.

So, of these, decide what's important to you; then you can brainstorm. It's really fun to sit around with people and say, "What's possible? Given all of this technology and the state of the art, what could we do on a Web site?" You get this long list of really nifty things, and then somebody says, "Yes, but we've got limited resources."

Now it's time to prioritize. Which one of these is the most important? Given that, okay, let's accomplish this one first and use those neat ideas, and then in month three we'll do this one, and then in month four we'll do this one, and then this one. We've got a whole series of new things to add to our Web site which are public events for which you can send out a new press release — company.com now announces a new feature on their Web site. You can continue to attract attention back to your Web site; that's worthwhile.

But you've got to prioritize, you've got to decide why and then that will tell you who it's for. If it's for corporate image you want to feed to the press and to the industry analysts whatever it is that they want: the press releases, the deep background, the life story of the CEO, all the stuff your customers could care less about. But if corporate image is important to you and you want to make sure your story is told, give the press everything they need. Give potential investors, the people who are in charge of investor relations — get them involved. Obviously, customers and prospects for customer service — I have prospects up there very intentionally — customer service is one of the best tools that you have on a Web site to turn people from prospects into customers.

If I want to buy a roomful of chairs, and I go to one Web site and there is a bunch of marketing material on how fabulous their chairs are, and I go to the other Web site and there's not that much product information but there's a bunch of customer support services, I realize which company will be easier doing business with. If I become their customer, I have all this service available to me.

[Then there's the] buying decision. I talked to a guy who's trying to make a decision between a Compaq and a Dell machine, and he did that, he looked at the two. He wasn't just buying one, he was buying 250. He thought about the engineers that are going to come in after-hours and install and configure these things, pull the wires through the ceiling and plug all the printers in and try to make it all work — they're there off-hours, they're not going to be able to call the 800 number; but they're going to have access to the Web site, so which Web site is going to give them the most support?

The Compaq Web site had printer drivers; it had configuration advice; it had pictures on how to plug things in; and it had comments from other customers on experiences they had. He said, "Bingo." That made his buying decision; not because they went on and on about how wonderful their machines were, but because they offered lots of customer service.

What is it and who is it for? If you know who it's for now you can try to make some assumptions. You can go out and do a little research and figure out who those people are and

how they accessed the Web site. Are they on a 14.4 modem? Do they have a 10-megabit connection so they can put up video — heck, they'll like it, they'll appreciate it. But maybe they're not... Let's say you're selling UNIX workstations. Who buys UNIX workstations? People who already have a lot of UNIX workstations, primarily. Nice big screens, fast connections, corporate LANs. Gee, go ahead and fill up your Web site with a bunch of real high-speed capable stuff — nifty.

But remember that the engineer who is on his 10-megabit line in the afternoon goes home in the evening and has just a couple more things he wants to finish up, and he's on a 14.4 modem. And he gets so annoyed that he goes out the next day and buys a 28.8 modem; he tries that and you still can't do video on that. You're still not going to do comfortable audio on that. So be real careful about that.

Are these people dialing in or are they permanently connected? Are they Super VGA, are they UNIX? If you take a screen that's just gorgeous on a Sun workstation and you put it on a laptop, you can't see much of it because they blow it up to get all the pixels in there. Are they coming through America Online or are they Netscape? If you need to have something that is formatted to look like the *Wall Street Journal* then you need to use all the Netscape enhancements. It looks gorgeous and it's easy to access — unless you're coming through America Online, and then it looks like a mistake.

You've got to make the actual decision. These people said, "We don't care about America Online — CompuServe allows their people to use Netscape. The majority of the people use Netscape. In fact, I just love statistics. You can draw any picture you want. I want to be very clear about what this picture is. Browsers used to select the random site link at Yahoo in September — that's who we're looking at. Now, these are clearly people who have more time on their hands than sense.

Well, I'm surfing the Web and I don't care where I want to go — it's random. [That person is] not likely to be our customer. But 79% of them are using Netscape; you have to decide that you don't care about the 10% who are on Mosaic, that out of every 100 people you don't care about the 10 folks who happen to come on your site in Mosaic and don't see it centered and can't use the frames and have a horrible time navigating because you're enhanced for Netscape.

Even worse, you don't care about the four people who are using text-only; when they come to your Web site, instead of your beautiful Home Page, they see the word "image" in brackets. They don't even know where they are. Is that okay? No, it's not.

The solution then is to allow people to choose for themselves what your Web site looks like. It's up to you to provide the choice. Here we have [Sylvia's Ghost], which was appropriate for yesterday. Click on the Netscape version or the other. If you're using text-based, like Lynx, we have completely text-only pages. Well, if I'm on Netscape I might pick that one as well because it's faster; in fact, I might go up to Options and hit "Images Off" because I want to get at the information.

One of the things that Silicon Graphics learned was to put up a big graphic, because that's what they do for a living, and if you click on a Web site called Silicon Graphics you kind of expect a big picture, so you deserve it. But down at the bottom they had the blue text — the choices in text. And that's great, because you can do the picture, and you know if you click somewhere in the picture you're going to get more big pictures; and if you click on the text it will go to the text areas.

If I'm in Lynx, I see "Image" and then I've still got all of my choices there. And I talked to them and said, "Guys, please do me one favor? Take that button bar of the text and put it at the top so we don't have to wait at 14.4 for your front page to load before we get the options." And they did. So it's very quick; it's easy to make the choices.

I'm a Mozilla killa... Okay, I've got Mozilla 1.1 or later — give me the full-on, full-tilt, “enhanced for Mozilla” experience. Or Net Monster Free — no funny look — Net Monster. Here pal, no sirree, I'm doing just fine with my browser. Give me that, don't give me that chaotic stuff. I want the look and feel of standard HTML.

Give your people the option, let them tell you, and then keep track of your stats and how many people went to the text pages and how many to the Netscape pages. Then you can decide if you need to continue doing the dual development. Question?

W: [inaudible]

Jim Sterne: In this case, entirely. I have no idea what this Web site is about. But that's their Home Page.

W: I'm worried about the information I want to put on. The first thing they see is that they need to make all these selections — you can select the browser or if you want just text or not — and I'm worried about that getting in the way.

Jim Sterne: There are two approaches. One is to make it subtle, like in the lower corner so that the person who really needs it can find it and it's available. The other option is the “front door” method. When somebody does `www.company.com` they get an excruciatingly plain page that comes up in a snap that says, “High speed, medium speed, low speed, you pick.” And they don't even get a company message.

There's a little logo at the top that says they're headed in the right direction, but yes, you're forcing them into another click. It's not going to make them that happy, but if they're a common visitor they will bookmark the second page anyway or whichever second page they choose. It will always be thus, because next week we'll always be putting in extensions that nobody else has, because that's their method and it's how they're maintaining market share.

[Tape change]

M: [inaudible]

Jim Sterne: Some of the browsers announce themselves, like *Netscape* and *Enhanced Mosaic*. They send along information that says, “Oh, by the way, this is who I am.” And if you have a script in front of your Home Page it can say, Welcome, *Netscape* user, here's the nifty page.”

So you can do that with some, but you're not going to know unless you read the domain name who's coming from AOL — its browser doesn't announce itself yet. So you can automatically make some choices, although I think the *Air Mosaic*, *Enhanced Mosaic* is probably the closest to *Netscape*. They're trying to keep up in terms of handling all the extensions, but Oracle just announced a new browser yesterday, and we don't know what extensions they handle.

Keeping up is going to be really tough to do, especially when people start going off in different directions where — oh, it says Microsoft, we want you to try to keep up with us and different things the *Netscape* does. Now, you definitely have to do multiple development. It's like UNIX was — you create a piece of software and you compile it for this UNIX and that UNIX and it runs all over — no way. You have to go in there and tweak code to make sure that it will run under the different operating systems. You've got to tweak code to make sure it operates on the different browsers. And I say let the customer self-select.

[The Internet is a] two-way street, not a broadcast medium. You have just put life, soul and all kinds of additional resources into putting up a really nice Web page — making it fun, useful, easy to navigate, and full of good information. Get something in return. Make them pay a little bit for that. By that I mean with a currency they have, which is, number one, their time. If you do a good job they will pay you with their attention; and if you do a really good job they'll also pay you with information about themselves.

I usually recommend that people set up three-tiered or more levels of stuff that's available on that one site. The first tier is to attract attention and get people to show-up — it's free and available, come and look around, the front door of our store is open.

The second level is, "Here are some really nifty things that a lot of people would like, so in order to get at this we want you to reveal some information about yourself. Maybe we'll go all the way to name and address because we want to put you on our direct mail list and send you junk. But, also, we want to know how you feel about these products; we want to know how you're assessing the system and whether you think it's fast enough, to give us feedback about our Web site." Make them reveal something about themselves.

The third tier is real, live, important, valuable information — whatever it might be for different companies. It might be a report on a survey that you've done recently; it might be not just the white paper but the extensive concepts and facilities, or something which you want people to actually pay for.

A lot of us are in the information industry, and you publish that and you get people to actually come up with dollars for it. So there's the free stuff. There's the "give us a few answers and you can have this." The worst case of this that I saw was CNet. You've seen CNet on television, a new show with Richard Hart. They have a monster Web site — interesting stuff, but when they first went live they wanted you to register, they wanted to get your e-mail address. In order to encourage you to register, if you did then you could download the 4-megabyte computer animation of the Brown/Goldman killing. It was gruesome, just astonishing bad taste. Their servers were overwhelmed by people registering and downloading it. Unbelievable.

Here's a neat example. Everybody knows what to do here — it's a business reply card. I like it because it's familiar, all the way down to the "no postage necessary if used through the Internet."

Here is... I don't know if you remember the DealerNet car giveaway, but they did something interesting. Yes, they wanted name, address, e-mail or they wouldn't know where to send the car if you won; and then they wanted a little bit more information — the year, make, and model of your car.

Now, if I had the opportunity of winning a new car I would take an hour out of my Saturday and go down and test drive it and put my name in the barrel. Year, make, and model — that's all they wanted. It takes seconds to fill that out. Think of what they could have asked: when was the last time you bought a car, how many miles do you drive a year, how long is your commute, how many drivers in your family? Instead [it was] just year, make, and model; and oh, by the way, are you 14th floor or lower, 28.8 to 256, or more than 256 for access? So, can we use big pictures or not? And then would you like to subscribe to DealerNet's upcoming monthly mail newsletter, *The DealerNet Report*? And notice the default is "yes."

They have your e-mail address because you had to give them that. Now they're asking you if it's okay to send you marketing literature? Pretty nifty. If I'm in the market to buy a car, yes, I want their monthly report, I want to find out what's going on in the car industry for a while to get up to speed. But I guarantee you that the person who says they drive a 1968 VW Microbus gets a different newsletter than the [person who drives a] 1995 Mercedes Benz. It's the targeted marketing, the one-to-one marketing, the personalization.

Mama's Cucina, the Ragu folks, have about 45 questions on their survey and you don't get anything for it. It's just a survey; there's no prize, no contest, no sweepstakes, just "please answer these questions." How often do you eat pizza; how often do you cook it at home; how often do you order it delivered; when was the last time you bought pizza sauce in the store; how much did you pay; how many of our competitors' products have you tried; what do you think about them, on and on and on.

I called up and I talked to [Alicia Rockmore] and said, "Surely, you're kidding. People aren't going to spend five to ten minutes answering all these questions." [But they've been] overwhelmed with responses. People like the site; they think it's warm and friendly and they're willing to spend their time. They know that this is the way they can say thank you. If I like this site and buy a T-shirt, it sends a signal to Ragu that they're doing the right thing.

They said that the information that they're getting — yes, they recognize that it's statistically unscientific and it represents self-selected people who are willing to fill out surveys on a Web site. Okay, but there's enough good information. When 95% of this little skewed audience has the same opinion, chances are that's pretty representative of the rest of the population.

Chances are they ought to make their pizza sauce a little bit thicker to compete against their major competitor; and they said they've already started rolling some of that information into their product plans because of the number of responses that they're getting. The depth of the information that they're getting would have cost them hundreds of thousands of dollars in focus groups; so if you do a Web site right people will pay you back with their information.

There's another way that it's a two-way street at Mama's Cucina. This is Mama's favorite places; at any other Web site, when you see the button that says "Our favorite places," you know you're going to go to a blue page with that list of other sites on the Internet that we like, and we'll see you later. This is Mama's favorite places in Italy, where she has gone recently and stayed in a nice hotel, had lunch at a nice restaurant — and by the way, have you been to Italy recently? We want to hear your story.

Next time you go, you can click on "Milano" and look at 10 or 12 different versions of people who've been there in the last couple of weeks, and they say, "Around the corner from the fountain behind the barbershop there's this really nice trattoria, they have great linguini, ask for Giuseppe and tell him I sent you." You can't get that out of *Froemmers on Europe on \$150 a Day* — I don't know what it is now. You get this and it's real current, and it's a way of asking the audience to participate. If I added my restaurant review to this Web site, it's built the loyalty bond real strong because I now am a publisher on their Web site.

Then she asks you to answer. "Mama, write to me when Ragu offers coupons in the newspaper or features new items on the Web site or introduces a new flavor or product." You enter your e-mail address and your name. I am not only agreeing to accept marketing literature, but I'm telling her what kind of marketing literature I want. So, yes, I checked that I want to be notified when the Web site is updated. And the announcements are really cute. "Yooohoo, it's Mama from www.eat.com; we've added some really new stuff. Come and see it. We've got this, this and this, and we're really looking forward to seeing you again, just remember to wipe your feet."

It's not only a two-way street, but if you're starting to collect information about people you can personalize it for those people. As Chris talked about, Bank of America had "build your own bank," a very powerful statement on a Home Page. I'm going to configure their bank to satisfy me.

Here is an area that I'm slightly interested in at this moment — a bookstore on the Internet. One million titles come in; search our stacks, search our shelves by keyword, author,

title, subject. Use our full-featured search form, use our search language — for those computer scientists — to look at the award winners and the bestsellers and read customer reviews.

So you're not just stuck trying to figure out what the *New York Review of Books* said; you can see what the average person who has Internet access and a Web browser thinks about those titles. And by the way, here's some staff favorites by category, so you can see what the people who work there read and like.

If you do a search on Internet marketing you might find my book, which you can add to your shopping basket, but also you can look for similar books by the following subjects: Internet Marketing, WorldWide Web information, Computer Commerce, Computer Networks, and General Marketing. Click off which ones you want and hit the button.

If you're in the store and you go to the front desk and you say, "Where's Jim Sterne's book?" They'll say, "It's over in that section." And you go to that section and say, "Oh, look at all these other books in the same category with the same subject matter." It's hard to do that on a Web site, but they've found a really good way to do it. Find the book you're interested in and say, "Yes, I want to see others that are like it."

There's also the personal information service so you can go here and say, "Gee, I want to see other subjects on Internet marketing. Here's my e-mail address — any time a new book is published that falls into that category I want you to send me an e-mail." This isn't marketing anymore, this is — I'm really interested. This is a service. This is valuable to me. I especially want to know if an author named Jim Sterne publishes a new book — I'd like to know that first. Well, maybe you want to know when the next John Le Carre comes out, or you want the next Tom Clancy; they'll tell you and boom, it will come into your mailbox. It's personalized.

This is just the beginning. We are able to take the next step, which is: "Good to see you again, Dave. We know when you were last at our Web site because you logged in and identified yourself. We know what you haven't seen since you were last here, and we can create a page on the fly to show you the new stuff. We know what products you're interested in because last time you looked at the band saws; well, this time we're having a sale on hand drills. Maybe you'd like to take a look at that."

"Here's some information on your investment portfolio," if we happen to be your bank. "We can go out and instantly fetch the latest stock quotes and show you the results, and it's personalized to you."

"Here's the status of the order you placed several weeks ago, on-line, accessing the glass house data center and supplying the information." America Online already does this: "We notice that you're using an older version of software," and boom, download the new version.

Let's allow the user to create their own Web site for their own purposes. So make it fun, useful, or interesting; easy, fresh, targeted; a two-way street, and personal because this is your Web site, this is your Web site using those six rules. Are there any questions? Have you heard it all before? Does this all sound familiar? Some yes, some no. Well, let me ask, because I'm curious, what kinds of things can you offer your customers? What might you do on your Web site that is a service to people? Somebody raise your hand.

M: [inaudible]

Jim Sterne: So I put in the kind of car that I have and my zip code and you'll show me the dealer where I can find the particular car battery. That's good. If I'm interested in buying a car battery I might just have the guy at the local gas station do it, but you know I'm going to pay twice as much for that than if I just go to the store and buy it myself. I can go learn from your Web site which kind of battery is going to work best in my car and where I can find it. That's a good one. Who else?

W: [inaudible]

Jim Sterne: So if I log in, I can see a couple of choices. First of all, what on earth is an HMO these days? They change so fast. Is my doctor in your HMO plan? Everybody wants to know that one because if you switch plans, geez, am I going to get to keep my doctor? That's information that you can keep absolutely current. I don't know how many times I've gotten a little booklet, called them up and they said, "No, we're not anymore." So that's vital.

I think your idea of once you have somebody enrolled and you know their medical history, you know the things they're going to be interested in, you know that when you create a menu of options, you can look at their customer record and say, "We'll weigh these things differently."

They're going to be more interested in this ailment and this remedy, so we'll put those at the top of the list. That's a nice way to do it. Also, in health care you have a grand opportunity to create communities of people. I don't know how many stories I've heard from folks who have gone to the Internet, which is a splendid place for group therapy. Unfortunately, it's not managed — it's just a bunch of people who have common problems talking about them, which is a fabulous tool.

I'm not saying we're going to put therapists out of business, but support groups are fabulous out there because you're behind the safety of your terminal in a room of strangers, and you can really pour out your heart — these are the problems that I have because of this condition. When somebody else from somewhere else in the world says, "Gee, I had that experience too, and I found this worked for me." Wow. And now they know that they can find that on your Web site. Very powerful, very useful — that's a gift out to the community.

W: [inaudible]

Jim Sterne: Mediated discussions are terrific, but are labor-intensive because people like to talk; you're going to find that you have to be there kind of on a twice-a-day basis to see what comes in and filter which ones you're going to post. So make sure that you've set aside some resource for that before jumping into it. If the response is really good, you're going to have trouble managing it.

But if you do, and if I'm one of the resources that is managing this discussion — it could be product information, product feature discussion group, any kind of focus group on the Internet — if I'm responsible for managing it, and something pops up that I'm unsure how the company wants to respond, I can forward it to the right department head. If it's a technical issue or medical issue I'm not sure about, I can forward it to a participating doctor and get the right answer and get it back quickly. That's wonderful. It's a two-way personal communication medium. It's a great thing to do on a Web site. Who else?

M: [inaudible]

Jim Sterne: I've heard that one of the most popular things out there are people who form [groups] around collectibles — I collect Elvis stuff or I collect glass paperweights, I collect Barbie dolls, whatever. And even if it's a little tiny subject matter you can find a lot of people who are really interested in it. If you're keeping track for me that I'm interested in the potential of picking up distressed properties, that's a real service to me — you're a clipping service, but even more so. You're not just looking at the news, you're looking at the marketplace for me

and making me aware of potential deals and hopefully taking a cut off the back end. A valuable service.

Okay, who here is having a lot of trouble thinking what you might do to make your Web site special? Over here in the corner.

M: [inaudible]

Jim Sterne: A commercial real estate builder. Nothing exciting or new or fun you can do in real estate?

M: [inaudible]

Jim Sterne: This developer puts up a Web site. Who is the audience? Are we looking for buyers or for investors? We're looking for people who are going to buy these houses. Okay, well, the first thing that comes to mind is that you'll want to get on a public relations campaign to seed all those places out there that are real estate-connected so that people know that the want ad shows up that they click on. It says, "Oh, there's a house in this particular geographic area, now come and take a tour of the house. And by the way, we have 12 units that we haven't started yet, and we're willing to let you configure them specially — here are the floor plan options, you can move this here or that there. Go ahead and click around and create your own home." That would be fun.

"Here are some trees you can plant around it." In fact, I don't know if you've seen that landscape piece of software where you specify the plants that you plant, and you see it five years later and ten years later — that would be a kick on a Web site. Custom design your own home in this building development; landscape it on the Web and decide what color you want to paint it, what kind of roof you want to put on it. Get them to own it before they've even talked to the sales rep.

M: [inaudible]

Jim Sterne: Absolutely, put in support for financials. Here's something that I've seen a couple of companies do. If I were a real estate developer I wouldn't want to put a lot of time into writing code that would do amortization schedules, because it's not real straightforward and simple. There are a lot of Web sites out there that will do that. But I've just opened the door for them to go bye-bye. Instead, what I've seen happen is that the people who do the calculations provide the code that lives on your server — "properly identified and brought to you by, courtesy of" — and you can go there if you want to, but you can stay here and do the calculation and go back and look at your new home. That's a good one.

M: [inaudible]

Jim Sterne: Pre-qualify to make sure that you're financially capable. You're pre-qualifying the folks that can't afford it, the folks who want to do some different kind of financing. The other thing you might hook in is relocation services. Why is somebody going to buy a new home? Maybe because they have to move for job considerations, but what else? Tell me something about the geographic area; I want to know what the schools are, what the local government is like, and if he doesn't have developments in every part of the country then that's not an overwhelming task. Otherwise, it is.

M: [inaudible]

Jim Sterne: Auto insurance — yes, a necessary evil. What is your product positioning? How do you differentiate yourself? What do you offer?

M: [inaudible]

Jim Sterne: So you're limited geographically and you're regulated for price. So what distinguishes you from your competitors? I like the sound of that — customer service. It just rings a bell.

M: [inaudible]

Jim Sterne: So geographically you're regulated for price, you can only sell through agents, and you provide really great customer service. When I buy insurance what I'm focused on is what's the minimum I think I need to have so I don't have to spend too much; and I never ever think about what would it be like to actually have to use the service. What's it like to have to write an insurance claim form? That's like thinking about putting together your funeral service — I don't want to plan for having an accident.

I don't want to plan for having my house burn down. Besides being traumatic, it's difficult. So if you provide some information — hey, it's easy to work with us, here are the steps, here's what we've done for others, here's a picture of the van that will come to your house — you help to educate people. But I'm still trying to think of some technology — we've got a room full of expert help out here. You're buying insurance, what do you want to see?

M: [inaudible]

Jim Sterne: Especially in a regulated state. I would suggest that you hook up with the real estate guy — are you real estate people in Massachusetts? Darn, because relocation services... You're going to need different insurance.

M: [inaudible]

Jim Sterne: And if your agent is not on e-mail there is software out there now that, instead of sending an e-mail, it will print it into a fax — and your agent definitely has a fax machine. We know that.

M: [inaudible]

Jim Sterne: I'm going to put in my zip code and my home address and then I'll get specific rates back on car insurance for me. Plus, the other thing that I get in the mail every six months from my insurance agent is the update questionnaire. By the way, is your son driving now? Does he own his own car? Have you added on to your house? Have you made any physical improvements? It's just the way of going through and saying, gee, am I insured enough?

I can tell you that in Santa Barbara several years ago, and Oakland a couple of years later, there were large fires, and, of course, we had the earthquake down in Northridge. I can't tell you how many people bought insurance and put it in a safety deposit box and forgot about it, and when it was time to rebuild their home their insurance agents told them, "I'm sorry, you're only half insured because the value and price of homes has gone way up and you didn't keep up to date." If I'm an insurance customer that would be something valuable for me to do

— my own self-analysis when I was sure the agent wouldn't call me or pester me. I'll take a look for myself.

M: [inaudible]

Jim Sterne: That's interesting. There may be auto dealers that are on the Web, and wouldn't that be interesting to hook up with them? If I'm looking at buying a car — by the way, check out what my insurance would be. Gee, should I buy that Ferrari? Yeah, I can afford it but I can't afford the insurance.

M: [inaudible]

Jim Sterne: Ooh, actuarial information, accident information. Also, give me a button to click on the *Kelly Blue Book*, because if I'm buying a new car I'm probably selling my old one.

In order not to keep you here all day, we're going to move along to the next segment. Chris, do you want to regale this audience with some of your views of what's going to happen in the future?

Chris VandenBerg: There's some interesting topics, things like the standards bodies. There's a lot of talk right now on the standards bodies. Do we need to come up with a new mechanism or do we just use the old mechanisms, like the IATF? What are the benefits? Is there an upside and downside to anything? Are those organizations dead? I certainly wouldn't propose that they are, but things are changing rapidly; not necessarily by groups trying to control the way they're changing, but trying to push. Is that a bad thing?

That's probably one of the things we should talk about. I'm sure people have opinions. If you're a developer, one side says, "Gee, I'd really like to know what all the standard things are, so I know what to support. I think that's certainly what Mike's faced with. But you also want to show the coolest thing, and if somebody else has a tool set that supports a cooler thing than you can show you're going to say, "Gee, I want to support that."

There are a lot of dynamics to this whole thing — and what's the right way? I don't think there is a right way, but I think certainly there's going to be a lot of opinions. We're going to make this the opinion session, but I guess the goal is that the three of us have opinions. I promise you that we don't agree on everything; that would be really scary. But I guarantee that's not the case. During this session, if you want to slam things that Microsoft has done, fine, as long as we keep it on a factual basis, I'll discuss it.

The "registration wizard" does not steal your machine configuration, okay? I'll put that to bed right now. It doesn't do that. Okay, seriously, I just want to have a good discussion. That's why I came 4,000 miles — to have a good discussion. There are things I want to talk about, but I don't want to keep it "Microsoft-centric." I want to involve these guys. They have some really good ideas, and we've had some good discussions.

Can we do that? Is that realistic? I am going to try and make some people mad with some of my slides, because that always starts the discussion going well. Actually, why don't we try to envision a thing like the McLaughlin Group, where they say, "We're going to sell out — predictions, Eleanor?" We kind of do that kind of thing right here, where you get two minutes to sum everything up and it's usually very outrageous.

Predictions. We talk a lot about the U.S. — we're very "U.S.-centric." We, as a company, have kind of a typical view. By the way, and this is anecdotal certainly, we come up with an application for the U.S. and sell it all over the world saying it's a global application. That's a limited view, and we're trying to get much better. In general, though, there are a lot of

trends, as I alluded to this morning, to expand the Internet and use it as a national competitive advantage.

Countries like Singapore — everybody thinks, “By the way, in Singapore the Internet is censored.” I’m here to say that that’s not true, folks. Somebody’s kind of presenting the view that they want to hear. There are three Internet providers [in that country], and they view it — the government is investing in the infrastructure now in a huge way, and they believe in making sure that the parents enforce certain standards. But the point is, yes, you might say it’s an oppressive society, but they view the Internet and communications as a very fundamental competitive advantage.

I’ve seen that [situation] replicated in other areas of the world. Does anyone right now have an application or a use that you foresee, or you’re counting on this happening, for trying to reach globally? Today I think we assume that the rest of the world has the same connectivity as the U.S. Sorry, it’s not the case, and if you’re assuming that then you have an incorrect assumption. It’s still expensive everywhere else. This thing about Europe being one harmonious area and everybody loves [each other] — that is bull! They hate each other. It’s all monopolies. That’s a strong statement. They are trying to protect their monopolies, and whether it’s Germany or France they still are keeping up the status quo, or they’re trying to. That’s going to change to a certain extent, and the Internet is driving a lot of that change.

If you’re counting on widespread connectivity, I think you’ll be in better shape in ‘96. I was at the Telecom Show, which is the big show in Geneva every four years, and they spent 35 million dollars on booths. Just the booths. These are the big companies. IBM spent a bunch on theirs, too, but that’s another story. Everybody was making IP announcements — dial-up IP — which was very interesting. Four years ago nobody would have foreseen that.

Is anybody looking for that kind of connectivity or counting on that? And if so, when? Are you trying to extend your reach globally? The Internet makes it a lot easier, as long as you have a [inaudible]. So you’re trying [for] leverage. How would it help you?

W: [inaudible]

Chris Vandenberg: China — there are huge efforts right now to bring the Internet to China. In many cases, though — in Eastern Europe the phone system is miserable and they use the Internet instead of phones because it’s more reliable. That’s kind of an interesting concept.

W: [inaudible]

Chris Vandenberg: And what language do you want it in? Localized content is a big issue in Europe right now. It will be very interesting to see if America Online is successful going over [to Europe] as America Online. Their president for Europe went over and did a speech in Geneva where he announced boldly that America Online was coming to Europe. I chatted with about 10 Europeans who said, “Why don’t you go on home? We really don’t want you over here.”

M: [inaudible]

Chris Vandenberg: There are a couple of competitors, but the point is that I got a real sense from the European folks that I talked to — and they came from a wide variety of backgrounds and interest levels — that they wanted European content that had relevance to them. There’s some global appeal to things — maybe *Hot Wired* appeals to everybody — but local content is really where they saw the majority of people in their country spending their time.

If you're trying to develop content that you envision having global appeal, you almost need to start thinking about localization from a language standpoint, but possibly even [from a] distribution [standpoint].

If you have subsidiaries in other countries, you need to start to think about running that content in those countries. The international line costs of running Internet service, by the way, are typically 40% to 45% of the cost for running an Internet service. In the U.S. we kind of think it's free — you know, the backbone is just kind of there and it just works. But it's a much lower overall percentage of the cost.

Internationally, Australia is two million bucks a year for a T-1. That really hits the bottom line of an Internet service provider. So if you are thinking about that, that's something to bear in mind. There are going to be a lot more people on-line, so I predict you'll get a lot more eyeballs from places that you didn't envision.

You may find appeal for your information and your product that you didn't think you were going to get, and you have to choose whether you want to respond to it. Certainly, if you're going to engage a customer base overseas that's a whole different proposition.

M: There's the thought that English has become the language of commerce around the world, and now it will be even more so.

Chris Vandenberg: Well, I wouldn't bet on that. I think you're making a big mistake if you're going in with a business plan that says that. Microsoft's number two market is Japan, after the U.S.

M: [inaudible]

Chris Vandenberg: I don't even know, to be honest with you, I just know that they are number two. I'd rather tell you I don't know than make something up. It's a very large market. Internationally, it's split pretty evenly between domestic and all of international, so it may be 10% or 15% — a good chunk of 6 billion dollars. But I don't know what the figures are. And they do have some localization, but I guess I'd have a question for those of you developing: do all the servers support double-byte character sets yet?

M: [inaudible]

Chris Vandenberg: Good point. You might want to check on that if you're serious because it's really hard to do that without double-byte character sets.

[Tape change]

Chris Vandenberg: That's a good point.

M: [inaudible]

Chris Vandenberg: I would think [in terms of] publishing, though, that there's an opportunity here because if you were doing physical distribution — as Nicholas [Negriponte] says, “atoms versus bits” — the costs for international distribution are huge, and the barriers of shipping are, too. Or if you're going to establish a satellite-based distribution system for the content, it's huge.

Transporting bits is pretty cheap, so it may actually offer the opportunity for publication if they can be successfully localized — and I'm not minimizing that, [because] that could be a ton of work and they're a very tricky challenge. But if you can do it, the distribution barriers are really a lot lower than having to have trucks rumble through the streets of Paris. So that's something to consider.

Prediction two — we've beat that one to death. I know, you spend a lot of time on [inaudible] and you're really upset. I believe that this is going to happen, and I hope that we have a pitched discussion on this. Those of you who are good at it, that's great, you may be able to still extend that, but I think that ultimately you're going to have a choice if you want to continue to spend your time understanding the internals or doing really cool things with the tools that are provided — assuming they meet the need, and if they don't meet the need you'll still end up doing it yourself.

[Panel]: We're not writing in Basic anymore because we have wonderful tools for doing Visual Basic, and we're getting to the point where if you can drag and drop stuff everybody will be able to create their own Home Page. But you still have sophisticated capabilities behind it. We're with *Java*, and with the new tools that are coming on — yes, you need to be a programmer to put together a solid Web site that can deal with the data that's coming in and then shoot it back into the database and the corporate data center. Yes, the HTML, the “what does it look like” is going to be a piece of cake. But all the back-end stuff, which is what's going to make a great Web site, is still going to require programming.

Chris Vandenberg: For the component integration, I wouldn't disagree with that. I'm talking about the authoring environment.

M: [inaudible]

Chris Vandenberg: There are, in fact, several approaches. Once again, I'm not going to sell anything, so you decide what's appropriate. But there are several approaches. I mean, *Netscape* is looking at their [inaudible] to provide a scripting capability.

Java does some neat things, but it doesn't do everything. And if you read the papers, *Java* is like the Second Coming. I'm sorry, that's crap. It's an interpretive language; it may download some components, it does some things very well and it's a really neat idea... Jim [Gossling] came up with some great stuff, but it's another thing, it's another cool thing, but [just] another thing.

M: [inaudible]

Chris Vandenberg: I think all the solutions are being envisioned to essentially have components that get downloaded to your machine to do really cool things at that time, and then away they go. And your environment has some control over them. There needs to be some kind of — Jim and I were carrying on this e-mail dialogue about this. There almost needs to be like an object library of things that have been imbedded and tested, and we know these things are not Trojan horse material. They're sent over in encrypted methods with full end-to-end security, but there's a bunch of models, and the marketplace will make the choice.

M: [inaudible]

[Panel]: It's got to have three things: it's got to be economically viable to validate and shift in code [so that it] is secure; it has to be really fast; and it has to be invisible so that there is no mental overhead [inaudible].

Chris Vandenberg: Yes, the user shouldn't know anything about it other than maybe making a choice whether they want to allow it to happen. But there's an analogy here; has anything that's happened on the Internet to this point killed shareware? There's still a bunch of really good places where you can go out and download shareware. you know the risks and you make the choice, or you can go down and buy it from some place. I don't see those grass roots developers — they're not going to go away. It's just "let the buyer beware."

Or if you want to run through some kind of a certification program that you run, or that Sun runs, or we run, then we'll bless that and our reputation will go with that chunk of code — whether it's an OCX or whatever, [and we'll say], "this will not blow your machine up, and this will not steal from the registration wizard all the stuff that we said we weren't taking before." Whatever — it can be handled in a lot of different ways.

Michael Bauer: Does that mean we're going to get an HTML headstone for the computer museum?

Chris Vandenberg: No, that may still be the underlying mechanism. That's not the point. It still runs HTML; the question is, do you have to know it?

Michael Bauer: Well, who are "you"? There are lots of different "yous". You as the contributor aren't the developer.

Chris Vandenberg: I believe, fundamentally — Mike and I [both believe this], and that's why he's very good in his company — it is very well going to mean having fundamentally different view of how to approach technology. To me, technology is like razor blades; for him he shaves with it. Me, every time I touch it it cuts me. He's good at that; he's mastered it so that it doesn't cut him and he's turned it to his advantage. Certainly, that's what his company is very good at.

M: [inaudible]

Chris Vandenberg: Six months to a year, a year on the outside. I mean, it's one thing to have one company do a product, but then it's another thing to have people accept it and all that stuff.

M: [inaudible]

Chris Vandenberg: Because if you can pull in objects — whether it's *Java* applets or OCX is really irrelevant — if you can pull in objects that other people have developed to do really cool things, if I can pull in an object that does [something like] pick the hot thing on the Web today... What's the coolest thing that you're seeing today? Maybe in-line-streaming video. If I can just drag in an OCX control or a *Java* applet that provides streaming video, I just drag that in and I don't care about the underlying mechanism, and I don't need to touch the technology. I can just design. As a designer, I think in terms of functional blocks. I don't care about the plumbing underneath; I assume it's going to work. And these are developed by a wide variety of third-party developers that know the details and make it work.

Maybe your group is one of those that says, "Okay, we have expertise in these five areas and we're going to develop these little object modules and then resell them. That's great too,

because what you're doing there is passing your value-add to people that don't want to replicate it, or can't.

M: [inaudible]

Chris VandenBerg: It will take a while, and it's not just the product — it's the training and getting people to provide solutions. The technology is fine and dandy, once again, as long as it solves the problem.

Michael Bauer: *Netscape* has picked a number — 70% of the market — of a very small market that is very anxious to be the first one using it, and the rest of the market has got to be 9 billion people who don't have anything yet, but are waiting to do the same once the product has proven itself. [These people have the attitude], "Before I get involved I want to see something is going to be around for a while."

Chris VandenBerg: I mean, for Mike and his company I can understand the dilemma of choosing. You've almost got to — because of limited resources, (well, everybody has limited resources) — you've got to make a wise choice in where you're going to develop. It's hard. The market is immature at this point, and it's a crashout.

M: [inaudible]

Chris VandenBerg: Until the market makes a choice.

[Panel]: The market did make a choice, and Windows basically won out, and now we're going to replay that whole thing again in the browsers.

Chris VandenBerg: Because the market wants to make another choice.

M: [inaudible]

[Panel]: Yes, but now the Internet no longer belongs to technologists and to standardizers. It belongs to the marketplace. And the marketplace is going to go with *Netscape*, even if it's nonstandard, because it's the coolest, latest thing.

Chris VandenBerg: I really want to push back on this point, having been involved in the IATF and Internet standards process on more than one occasion. There were RFCs published for informational purposes, and if 10 companies took it there were 10 implementations that were done. The first time they plugged in they didn't work — we had to get together and do bake-offs. But after you established the base-level functionality you could still add your own thing.

There's kind of a "lowest common denominator" functionality. The standards process is there to ensure that level, and then everybody still enhances and optimizes and differentiates their own way. If they're successful in the marketplace, they can build critical mass and then they can dictate — that's a strong term — they can say what they want the standard to be. And once again, what do you do? Do you say you're going to wait for the company with 1% market share to try and coordinate with us? It's a difficult question.

M: [inaudible]

Chris Vandenberg: Anytime you put content out on the Internet, whatever that content is, I consider that authoring.

M: [inaudible]

[Panel]: I think of authoring as experiencing, not just the content. You're developing an interactive [inaudible].

Chris Vandenberg: [I have a] closing comment on that: design and content don't have to be linked. I can have a very rich design and a nice library of objects, and then the content changes on the fly. Today we're kind of hacking our way to that, but that's because, fundamentally, the protocol and the tool set went in with that assumption that they were linked. It doesn't have to be.

Number three — and this is actually kind of my favorite — yes, people will make a lot of money, but they won't do it by becoming ISPs and putting their foot up on the Rolls Royce and saying, "I made millions of dollars, don't you want to, too?" They'll work hard. They'll come up with really cool, innovative ideas, like with Mike's company, like what Jim's doing. They'll add value. They'll earn it.

Everybody seems to be looking at this whole Internet thing. We actually have a really interesting video I tried to [bring], but it's so good that they only let Bill use it. It's called *The State of the Art*, which we did actually for the analysts because they kept saying, "What's all this Internet stuff? What's Microsoft doing?" It's really good because it has clips, like Bill saying, "Anybody can make millions in the Internet — I've done it." Things like that. And then it's got Spielberg and Katzenberg and those guys saying, "We did it, too," and that kind of thing. And it's actually very funny.

But the point is, if you add value in places and you can build a viable business model, you'll make money at this stuff — or your company will be more productive, which adds money to the bottom line. There really isn't any magic about it, and it's just kind of amazing that all these people are flocking in now saying, "What's the thing here? What's the mystery about all this? Where are we going to make our millions?" It's the same thing you've been doing, adding value at the right places with a good business model.

[Panel]: Think about if direct mail suddenly happened; now we all have a way of [inaudible]. We can all go out and get rich right now; we're all creative. There's a fine art to creating good direct mail. Same thing on the Internet, no different.

Chris Vandenberg: I'll turn it over to you guys now.

Jim Sterne: The first [prediction is] by Nicholas [Negreponte]: By the year 2000 there will be one billion people on the Internet. I like the keynote guy from Sun; a couple of days ago he said, "The new-generation IP address system is going to allow for 1,625 IP addresses per square yard of the planet." That ought to be enough.

I like to quote Mark Gibbs, who is an Internet guru and author who said that when [Elvis] died there were 43 Elvis impersonators, and today there are 43,000 Elvis impersonators. By the year 2010 every third person will be an Elvis impersonator. Then one of my favorites [is from] Michael Bauer: "By the year 2020 there will be more computers on the Internet than particles of matter in the universe." Thank you, I use that all the time and everybody agrees.

Okay, so here's the short-term/long-term. E-mail in the Web will be expected from you, and all services will be combined. Let's go through these real quick... The services will be

combined: you're going to see the browser have the e-mail, have the Web access, have the audio, have the video. If you've been by the Netscape booth, you know this is old news. So much for short-term predictions.

[With] VRML we'll be able to graphically go out and 3-D our way around; and if you can figure out a way that being 3-D adds value, I want to know about it. Of course, this job — we all know that's exciting. The coffee cup can jump around, which from a marketing and grab-your-attention perspective is good. But again, I've got my ears wide open and I want to hear about applications, because I think that this kind of imbedded programming is a good thing. I think you can put a spreadsheet on your Web page that I can type in my age and it will tell me what my insurance is going to cost. So I'm interested to hear what people are going to use that for.

M: [inaudible]

Jim Sterne: Right, so it's a neat technology that's fun to look at. But if I'm trying to buy something and it's keeping me away from the product, it's slowing me down. So that's a personal problem I have.

[With] imbedded access, I think browsers are going to disappear. It's not going to take very long. In Microsoft Word, if you click on the imbedded URL, it becomes the browser. Excel becomes the browser — your browsers are going to get imbedded in all of your applications.

[I also have some] "Help" and "Clip Art" examples. If I click on Help, instead of going to the five megabytes of Help on my disk I want it to go back to headquarters and take my last 25 keystrokes with it, so it can come back and say, "Oh, well, you jerk, this is what you did wrong." And I want it to give me the latest help.

Now I also think that access is going to be imbedded. If you saw what Quicken has just come out with, their latest release has Internet access. And you know that's old news, too. So if everything's changing so fast, if there's new technology all of the time, if there's no standards, why should I do this stuff now? The answer is because you've got to learn the human side of it.

You have to know who in your organization is going to be responsible for doing it. What is it like interacting with people electronically? It doesn't matter if it's through the cable TV or if it's Internet, or it's interactive or whatever — relating to people through computers is now happening, and there's a lot of the human side of it to learn regardless of the technology.

It is going to open up the company so that people are going to expect access to your data, and to their data, to your data about them, to your processes, your procedures, your policies. They're going to be able to instantly tell the boss that you did something wrong; you're not going to be able to hide behind your desk anymore. It's going to be an interesting world.

As I mentioned earlier, we're going to have the ability to personalize it. And that's really where we're going to end up with this thing — where you're going to get nine-tenths of the way through a customer service interaction and the computer-generated person on the screen is going to say, "Gee, you know what? I don't know. Let me go get a human being."

We want access to policy. I want to know why your company has policies that keep me from doing business. Why did I have to wait so long? Why can't I have this order split up the way I want? Because if I call up and I say I need 200 of them shipped tomorrow and the answer is no, I want to know why, because maybe the answer is that you asked for blue. "If you want it in green, you can have it tomorrow."

"Oh, great, I'll take it in green." But you've got to provide that kind of answer to the "why" questions for people.

They want — they being the public and your customers — and are going to expect to have an impact on your product decisions. They're going to expect to be able to say, "Gee, I'll

pay more if I can get it sooner; maybe you'll change your production schedule for me." That will happen automatically; it will come into your system. Benetton Clothing stores looks at what colors sold every day and uses that information to determine which dyes they run the next day in the factory. That's going to happen in a lot more industries.

[I want to mention the issue of] personnel evaluation reporting. If I have a bad experience with somebody on the phone, I'm going to send off an e-mail to that person's boss, like now. The corporation is going to open up and your customers are going to become a lot more like stockholders, and they're going to insist that you change the way you do business if you want to continue doing business with them.

You get into science fiction. Long-term, you'd all be at home right now with your 3-D goggles and your stereo headphones; but now we get into some difficult problems. If I look into a camera, it looks like I'm looking right at you. In this situation, if I move my eyes a fraction of an inch, you know I'm not looking at you anymore, I'm looking at [another person]. And you can all tell that this is tough, difficult technology, but we're going to get there. It's going to be this experience where you can go off in the corner with people and chat about it over a glass of water and then come back and sit down without leaving home.

Finally, [this is] my prediction on top of everything: by the year 2055 everything that can be connected will be. Anything that has a chip in it, anything that has any battery in it will be hooked up. I can safely say that because in 2055 I'll be 100 years old, and if I'm wrong you all can come and tell me.

W: [inaudible]

Jim Sterne: It will become more and more inclusive over time; it won't happen fast. You remember rural electrification, where people had to spend lots of money to run electricity out into the farm lands because they were left without? It's going to take a while. There's a lot of fiber that has to be laid to support that, and there's a lot of equipment. We heard this week about the \$500 computer — that is, the Internet computer. And if that's the case, and if that works, then that's going to enfranchise an awful lot of people. If it doesn't work it still costs \$3,000 for a computer, and that's going to keep a lot of people off.

M: [inaudible]

Jim Sterne: And on top of that, the day after tomorrow there will be a new manufacturing process that we cannot envision that will make it all so much cheaper that it will be silly to do without. We don't know.

M: [inaudible]

Jim Sterne: And therefore, from the marketing perspective, is my marketplace able to get on the Internet? Not "are they?" — because chances are they're not yet. But if they're capable and it's possible for them, then it's my responsibility to offer them something that's so useful that they will get on the Internet just to interact with my company. And then, "Oh, by the way, here's all this other neat surfing stuff."

But I'm going to offer them electronic data interchange that's valuable enough for all these neat resources. I don't care about the "Information Superhighway," but if I can track my Federal Express packages and I'm the shipping manager at my company, I'll get on the Internet just to do that. [Then it's], "Oh, look at all this other neat stuff."

M: [inaudible]

Michael Bauer: I think the Internet is like a language for communicating with people. It's a universal language, and everybody's just sort of starting to speak the same language, so there's a lot of value to that. But I also think the Internet's a virus, basically. It's out and it's — basically, when I think of the exponential growth and the fact that it's permeating in so many places, it really is functioning like a virus. So it's infecting people and infecting places because there's reason for that to be there. A lot of that reason I don't think is driven by the government, it's driven by the markets.

I think it's just a new, entertaining medium that we will see evolve. There are probably some entertaining geniuses out there that are figuring that there's a place that the Internet plays between print and between TV, somewhere in between using *Java* or using animation, and a collaborative cooperative type of environment. There's something very cool that is going to be coming out, I believe, because there are all the earmarks of that capability and they're going to need all the sort of constraints that's got them working.

A lot of new activities are, in some way, interactive cartoons. You've talked about people having *Avatar*. It may not be the VRML or some kind of combination thereof, but may be more animation in terms of the three-dimensional type of thing, of more convenient rhythms for the family. But I feel like there's going to be something along those lines, and technology's going to enable it. It's just going to be a new entertainment medium, and I think it's going to be something else, a entertainment medium that may be used in business settings as well.

Also, because it's a virus I think it's also going to mutate how people do things, especially how they do business. And the new, different ways of doing certain things are going to cause things to go away, like the bicycle messenger services — they've been going down for a while. As an industry they may get pushed down. Print catalogues and the cost of printing is just skyrocketing, and there may be some collusion going on because of it. But the Internet is like the Star Trek transporter for business: just go ahead and specify something to be created locally and distributed locally.

In terms of predictions, on a short term I think [what we'll see] are the new entertainment mediums that are going to come up that will enable us to have virtual trade shows. Hopefully, we'll do this kind of thing without physically having to travel someplace and cost so much money. [Meckler] may be depressed about that, but that's another issue.

M: [inaudible]

Michael Bauer: And why go? People are going to live in lots of places where it's comfortable to live, and the medium's going to be sophisticated enough and advanced enough to be able to do a lot of stuff. The only activities might be leisure activities, and now you're meeting people for business in business places.

M: [inaudible]

Michael Bauer: You're going to start paying for marketing, too; that's the one thing.

TUTORIAL

HOW SGML AND HTML REALLY FIT TOGETHER

SPEAKERS

Eric Severson

Vice President, Market Strategy & Corporate Development, Interleaf, Inc.

Diane Sandstrum

Training Manager, Central Region, Interleaf, Inc.

Eric Severson: We're going to be talking this morning about the standards that underlie Web technology, and we'll be doing this at a couple of different levels. One of those levels is kind of a high-level overview of what is this thing called HTML. How does it relate to SGML, which is what it is formerly based on? How do you resolve the apparent conflict between HTML and SGML that many of you have heard about or thought about? And then we'll also get down into a little more of a hands-on, detailed level about each of those standards.

But the idea here this morning is going to be, on the one hand, to give you a true tutorial about these standards so you can walk out of here and really know something about how SGML works in some detail, and how HTML fits into that in some detail. Probably even more important than that [will be for you] to get some insights into what goes on in the standards world and, down at the detailed level of these things, how those things actually impact application and business issues.

I'm Eric Severson with Interleaf. I'm also President of SGML Open, which is primarily an association of vendors and some key users of SGML products. It's made up of about 40 to 50 companies dedicated to promoting awareness of SGML, to helping people understand how SGML and HTML fit together and also help them understand the interoperability between SGML products. I'm going to start here with sort of an overview, but probably more than an overview, as a kind of a perspective on these issues so that when we go into the details — which will be done by Diane Sandstrum, also of Interleaf — you'll have a way to look at these things not just as a bunch of dry detail on the standards, but really for what this means to you.

If I were to describe the WorldWide Web in one word, I think I would do it like this: The WorldWide Web is cool. It is totally, outrageously, "way cool." You know, I don't think that I understood just how cool it really was until one night when I was surfing along the Web and ran into the Vatican Web site. I don't know about you, but I personally have never been to the Vatican; but here I was, and they were asking me questions like, "Do I want to go into the north wing and look at illustrated manuscripts from a thousand years ago — done by people who had no inkling of the kind of technology that I was accessing to get to the work that they did — or did I want to go into the south wing where there were other things to look at?"

I think I double-clicked and made my choice for the north wing. As I went through the halls and saw the thumbnail sketches of these things, I realized that I could click on something that I was interested in to get more information. I could zoom in and see it closer if I wanted to, and I could even, if I was willing to wait a few minutes, get a copy of it on my printer. That's way cool.

I don't think that I felt that same feeling of excitement about something like that since, well, maybe when I was about ten years old and someone gave me a short-wave radio for my birthday. You see, I was a kid who grew up on the western shore of Lake Michigan in the state of Wisconsin, in a little town called Manitowoc. It's a town with a lot of factories, a little bit of tourist business, and about 30-35,000 people. I had never heard anything but English spoken there, and even that not always so well. But here I was with my short-wave radio and I was hearing French and German and Spanish and Japanese, languages that I had only read about from

countries that I had only dreamed about. In one moment I went from being a little kid in this small town and feeling isolated to being connected to the world in a way that I had not experienced before.

I just can't help but think, in terms of setting perspective, that for all of these things we're going to talk about this morning, the explosion of interest in the WorldWide Web has something intrinsically to do with the same feeling of freedom and "connectedness" that I felt when I was a little kid with my short-wave radio.

But you know, when I was ten years old my mom didn't come to me and ask me to prove a business case for the time that I was spending with my short-wave radio. Now that I'm about four times that age, people do expect me to have a strong business reason for the interest that I would have in the WorldWide Web, because it's not just about connectedness, it is also a world of business. That's where we have to start from to get a perspective on what we are trying to do with these standards.

Why the heck are people interested in the Web in the first place? This is something that's pretty well accepted at this point: it's a killer infrastructure. It's all there for you. It works, you don't have to build it yourself, and we have the killer browsers like *Mosaic* or now *Netscape* or others that just come into being and are essentially free. The whole thing comes together. But those are only two components to make the whole picture work.

There's a third [reason] that we're still working on, and that's killer content. The content behind the Web, for the most part, has been missing so far. We have storefronts, advertising, interesting Home Pages that are sometimes works of graphic art and sometimes not so artistic; but it's relatively lightweight stuff that we're still cruising around on the Web. Even the Vatican is not really serious academic research material; it's a little closer to a theme park kind of treatment of the material.

We have some places where you can say, "Give me your Visa or MasterCard," and some people are using this internally to do some internal communication of memos and reports and that sort of thing. At one of the last Web conferences that I attended, I was informed that there are now five optometrists on the Web. That's kind of interesting as a way of showing the breadth of the Web, but not so interesting in showing the depth of the Web, because what people are talking about in the business world right now, which is still driving a lot of the interest in this, are more serious uses that include internal and external corporate publishing — which might include books and magazines available on the Web — and really more serious material for business research, academic research and so forth. They're even looking at the Web as the main way in which we would distribute information internally within corporations and government organizations.

If you don't take that point too seriously, I would ask you to consider what Bill Joy of Sun Microsystems said, quoted in *Information Week* this summer. He said, "With the hyperlink kind of paradigm that you see on the Web, you can imagine putting all of your corporate documentation on there, even design files for machines." Well, that's pretty amazing. I look at that and I say, you know, in the '60s people started trying to figure out how to organize business information on computers, and that started getting on a roll in the '70s. The MIS departments — or IS and IT, as they'd be called now — started really perfecting this idea of how you integrate all of this information within a corporation, and the '80s was the age of desktop publishing and integrated electronic publishing. We're getting into document management and all of this as we move into the '90s.

But suddenly, in one stroke, the Web has obviated the need for all of this, because with the hyperlink kind of paradigm that you see on the Web you can imagine putting all of your corporate documentation on there, even design files for machines. What does that mean? What

does that actually mean to say that this is what we're trying to do with the Web? That's part of the perspective that I want to get into here.

Now, again, what's the attraction? We try to answer this question, what's the attraction to the Web, in a little bit more detail. Well, it lets you do on-line distribution of simple information, and it does it with a pretty nice format — not the best that's ever been seen, but not bad. You can hyperlink, as Bill Joy said, and that's a very powerful way to get around information.

Most importantly, it's open access. As an IT director, for example, I don't have to go in and say, "How do I introduce this strange new technology among all of my users so that I can get them talking together?" They already know about the Web — you'd have to be dead not to know about the Web — and so this becomes a very, very open standard in a way that goes far beyond most efforts that you think of as standards efforts.

But where is it going? If we're really to do what Bill Joy has outlined in his vision, we're going to have to address the same issues that have been addressed in other attempts at integrating corporate and governmental kind of information. You've got to have some central source that drives a whole bunch of different things. The only output that you're going to be thinking of — well, the Web's not going to be the only output that you're thinking of. You're going to have paper production, you're going to have CD-ROMs, you're going to have interchange with other kinds of systems, and as you look at this crazy world that we live in, where every trade show like this that you go to you find that all the technology keeps changing and the vendors acquire each other and merge with each other, what are you going to do if you're going to build a long-term system?

So people are looking at standards like SGML as a way of saying, "Maybe I can protect my data over a long period of time where this doesn't depend on the vendor or the application that I happen to be using today." And, "I don't know all the ways my data is going to be used; today I have these four things I can tell you, one of which is the Web, but I may have ten other things next year — I don't know, so I need to have a format to store this stuff in that is capable of reuse." And it isn't just publishing; it's also linkages to other business systems. When you start to get into these things you start to be able to consider the question that Bill Joy raised. So I observed this, again, as a matter of perspective, that there's obviously no end of wild enthusiasm for all of the Web things that are going on.

There's certainly a very strong desire for simplicity in what we're doing. We want these standards to be simple. But in reality there's also a wide range of things that people are trying to do with the Web, and there's a big trade-off between these last two points. The desire for simplicity and the wide range of needs is leading up to people asking questions about this. When I go to conferences I see people stand up after keynote presentations and say, "Yeah, but what's the difference between SGML and HTML? And maybe more to the point, if you have HTML, do I still need to even think about SGML? Can I maybe forget about that now that I have HTML instead?" Well, we've got to look closer at SGML to figure out the answers to those questions.

As a real brief kind of overview, SGML is an international standard. It was brought on-line as an ISO standard in 1986. Its focus is on encoding the intrinsic nature of the data rather than encoding a particular kind of scheme that makes a vendor system run; that is, it's not like, let's say, a *WordPerfect* file full of command codes that lets *WordPerfect* present things on the screen or on paper as bold or centered. Instead, what it is is something that says, "This is a title." And then we can decide what command codes and whose system to apply to make that title look right for somebody. But the point is, this data is a title. And it's in that sense that SGML is a format that can get you a long-lived representation of your data. A typical SGML file has things in it like titles and headings, and lists and paragraphs and table rows and columns, and that kind of logical view of what's in the data.

I don't have a crystal ball or a time machine and I can't look ahead 50 years to see if that data would still be usable 50 years hence. Who knows what's going to happen even next year? But I can run a little thinking experiment that can help me decide whether that data is long-lived by going back in time 50 years and asking myself if 50 years ago, before any of this technology that you and I work with every day was even conceived of, if I had a file format that told me that something was a title, a heading, a list and so forth, would that have made sense to people then? Yeah. Would it make sense to people now? Yeah, because that part hasn't changed. It's all the technology surrounding it that's changed, and so I have some faith that 50 years from now something encoded in that simple kind of generic way would have some long life. That, more than anything else, is the idea behind SGML.

Another side effect of that is that if you've encoded things that way it's platform-independent, and it's open interchange between systems, between vendors and so forth. So, for all those reasons, it's not too surprising that SGML actually was the standard chosen as the basis for HTML. If we explore this sort of technical jungle of SGML a little bit further, look at it one level down, it doesn't take a very difficult document to understand what's going on.

Here's Disney's [Web site for] *The Lion King*. It says, "If you like Africa, you'll love Disney's new animated feature, *The Lion King*. *The Lion King* uses a new animation process..." and so forth. How would we have encoded that before SGML? Well, it would look something like this, probably uglier than this, but conceptually we would tend to say that we need to issue typesetting instructions or screen presentation instructions that somehow are embedded with the information and the file. We want to center and then embolden and underline this thing called *The Lion King*. Notice that nothing in that says why we would want to center and embolden and underline; we do that because we know that the reader is going to look at something that is centered, bold and underlined as a title. We've been trained to think of it that way, but the computer file knows nothing about that, it just knows how to present it so that you can process that information in your head.

Let me space down, and we indent and we say "italicize the word Africa." Why? Well, we're trying to cue the reader that there is something special about the word "Africa." What's special about it? Well, in this case, it turns out that it's in the glossary and you can actually look up more information about Africa if you'd like to. That's not as clear to the reader as the title part is, but you know that there's something about "Africa" if it's italicized. And then we go back to plain text, and "You'll love Disney's new..." and so forth.

That is the way that electronic publishing and word processing has essentially worked from the beginning. With SGML we take a radical new view, and it looks like this: we say sure, it's centered, bold and underlined, that's all fine, that's just the way you're telling the person how to read it. But the real point is that this is a title; and more than that, it is a title that is part of a larger object called the "chapter." The chapter starts here and it goes further down, but this little piece at the beginning is the chapter title. And it turns out that the word "Africa," while it may be italicized in the way we print it out, is important because it's a link to something else. So let's just say so, say that it's a link. I can choose to italicize it or do anything else I want with it, and 50 years from now this will still be a pretty meaningful representation of what that file was about, no matter what the technology was that was used to process it.

If we separate things that way, we then have another fundamental principal of SGML in play here — also the principal behind simpler stylesheets and so forth in word processors — which is to separate format from content. If I have my SGML telling me what the content is, I can then go and have many different representations of that data, maybe have two different looks on a printed page, maybe put the title in a button that I can double-click on if I want to expand for more information. All kinds of things are possible when I've done this kind of separation.

Furthermore, the more information that we get on the Web or inside of a corporation or anywhere, the more important it becomes to search things. If you're searching through a book and thumbing through things, you use a little more of your brain power than to start from the very beginning and just start reading every word until you find what you want; you start looking at chapters, and you look at the context and you kind of zero in as fast as you can to the most likely places in the book that you're going to find the information. If you're starting to do an electronics search and you're saying, "Well, I guess I'd want to search for anything that has a center and a bold code around it," that's a pretty rough-cut kind of electronic search. But if you can say, "I'm looking for this information only if it occurs within a title or within a chapter," now you're starting to home in electronically the same way you would if you're doing it manually. SGML also provides that kind of capability through this generic tagging.

And finally, once you've found something and you're able to present it in any way which you care to, because it's all been separated out logically for you, it becomes real possible to reuse the information. Here we have today's movies from this summer: *The Lion King* at 1:00 p.m. — and gosh, you know, I swear somebody wrote something really cool about *The Lion King* already. I don't want to have to make this up again; let me search through my database and pull out this little chunk that describes *The Lion King* and stick in my listing of today's movies. That's data reuse, and perhaps data reuse that could have been anticipated when we set up the original description of *The Lion King* — or maybe this was something that happened spontaneously.

But with these kinds of concepts behind the data it's not so hard to go pull that out. The reason for this is because, intrinsically, SGML is about objects. It takes a document which would otherwise be a stream of text characters, with some line breaks and maybe some proprietary formatting codes embedded within them, and it looks at them as a set of objects, objects which can be contained within each other. It chunks the information into objects that are generic, and it goes further than this — it puts them into a structure. This gives you another level of control over the information, as well as another level of browsing and search that is possible with the information. Unlike a stylesheet, this isn't just a chapter title followed by a paragraph followed by something else in the big linear stream of objects; this is actually a structure. The title lives within a paragraph, so if I find something in the title, when I do a search I can pull out the whole chapter because I know where it begins and ends. That's all marked up within the file for me because of this object notion of SGML. And this particular link lives within a paragraph.

Furthermore, I can see that the data has a problem if there's no title in it, because the title is required. Or I can say that you can't have two titles, you have to pick one. There are automated means to check the structure against those rules.

In SGML each of these structures is called a "Document-Type Definition," or a DTD. Diane is going to show what these things really look like, hands-on, a little bit later this morning; right now you can think of it essentially as a list of the kinds of objects that we want to capture in a document. I think that it's important to capture the notion of a title, so I've named something "Title." But also, it captures the rules by which these objects relate to each other; the title lives within a chapter and a paragraph and a link and so forth.

Each one of these applications of SGML or DTDs defines a specific use of SGML, which might be the way that SGML is standardized within a particular industry. The CALS effort, for example, is the United States Department of Defense use of SGML, and there are actually a set of applications that are all kind of related to each other that are defined there. [ATA ten0] is for the aerospace industry and defines the way, for example, that vendors like Boeing pass data on the 777 plane to United Airlines and so forth. It's an interchange standard that's a specific use of SGML with its own set of objects, its own structure. DocBook is something that's for on-line display of computer documentation.

I can make up any DTD, according to my own needs at my own organization, to describe my documents. It so happens that one of those DTDs or SGML application is HTML. HTML is a pretty simple one; it says that there's a heading section of a document followed by a body, and pretty much — although it's getting more complicated over time — pretty much what we're trying to do is capture paragraphs and links or URLs and so forth between documents. We also have some headings that are in there that can be displayed in a larger font, etc.

Nowadays, with HTML 3.0 — as Diane will show you — we're adding forms and tables and figures and a few other more complex typesetting objects, but pretty much HTML is this sort of a structure, and it is specified formally in an SGML document-type definition. So the technical answer to [the question], "do I still need SGML if I'm using HTML?" is that you already have SGML if you're using HTML. HTML, just like CALS, ATA, DocBook, etc., is an SGML application. It's a specific use of SGML.

So where does HTML fit in the jungle's food chain? Well, I like to look at this as kind of a level of accessibility and reusability question. Paper, of course, is the least accessible in an automated kind of fashion, and the least reusable. You can run it through a copy machine, you can go to a warehouse and have somebody find where you stored paper and that sort of thing; but in itself it's not a very good storage medium and that's why we're going electronic.

Adobe's PDF, which underlies *Acrobat*, is an electronic format that's not too much more sophisticated than paper. It's not revisable; it does a little bit of cross-linking and so forth, but pretty much you're seeing paper on a screen. As you move up through the revisable formats and get more and more explicit structure in linking, you begin to increase your ability to access and reuse data. And finally, SGML, which is the most powerful — but also the most complicated — of these things, kind of sits there as the ultimate in flexibility, accessibility and reusability. HTML, as it goes from HTML 2 to HTML 3 in the standards world, is kind of trying to figure out where to fit there. We'll show you more about what that means in detail.

These kinds of perspectives on it, though, add or lead people to ask the question, "Is HTML a general interchange format? Is that the one I could use to interchange data all over the place? It sure kind of seems like it, because we're talking WorldWide Web and interchange, right? And could it be the form in which I store my documents? Wouldn't that be good, because I'm going to use the Web for all kinds of things? Why don't I build an HTML repository so I can have access to all my HTML documents?" It sounds logical, but these are very, very important questions. How do you put these concepts together?

Right now, SGML is kind of in its own world. Mostly it's with high-end applications like the Department of Defense technical documentation and the Boeing 777 and so forth; it's not in very widespread use, although it's used in almost every major industry that you can think of in high-end applications. And HTML, of course, is all over the place. But these kind of live in their own worlds, and for the most part the people who are authoring data for SGML or other high-end publishing systems are not the same authors of the HTML data — or if they are, they're using a different system. And you see people winning product awards in the industry and so forth for finally giving something that will allow them to do HTML-authoring. So these are different worlds, but we need to put them together.

Here's one way, but I don't like this way. This is where HTML is in the center, and we author for HTML, and if we want to do something else with the data we figure out some way to bridge that to other systems, including SGML. Why not put HTML in the center? A lot of people are doing it. Why not?

Well, I'll tell you why not; because HTML is the lowest common denominator, a one-size-fits-all format, and if you talk to the developers, the editors of the standards like Dave Raggett and Don Connolly, for example, they will tell you that's what it's meant to be. That's the

whole point — it's supposed to be really simple. You should be able to type it out in a VI editor if you want to. Now, the question for you is, is that what you would want as the standard to store your data so that you're prepared for everything you might want to do with it? Your purpose for it is different than what Dave Regget and Don Connelly are saying.

Secondly, as they say in the HTML standards world, it's whoever shows up with working code that wins the day — and the standards can change overnight because somebody stays up at night and decides to make a change, and then broadcasts it the next day. If you happen to be on e-mail you'll see it, and if you're out of town, oh well, you'll catch it next time. That kind of volatility in the standard is a reflection of the explosion of this technology, and the fact that nobody wants to wait for some kind of formal standards process. I can understand that, and you can understand that; but is this the format that you want to base your information system on, when it's changing that fast? That's my question.

And third, if you do choose to base your information system on that you will have a fantastically difficult “up-translation” problem in the future. Now, what does up-translation mean? Think of it like Shakespeare: “To be or not to be, that is the question. Whether to suffer the slings and arrows of outrageous fortune...” Well, you see, there's a simpler way to express the world's library of Shakespeare. I could distill Shakespeare down into something that a first grader could understand, and would be much more efficient on a disk. It would be much more efficient to pass around a network by reducing Hamlet's soliloquy to the simple statement, “Is this jive worth it?” It's the same thing, really. If I ever wanted to put on a play with the real Shakespeare in there again, and I had reduced my storage and my library of Shakespeare to this form, how on earth could I ever recover the original from that?

That's the point. That's the point as to why HTML is not a sufficiently rich format in which to store all of your corporate information, despite Bill Joy's comment. You have a richness to your source information, and a richness to the application requirements that you are developing for, or that you as a manager are trying to manage. It goes far beyond the capabilities of HTML, and if you put HTML in between that and all of your formatting, search and reuse requirements, and get rid of the rich source because now you've gotten HTML, then you're forever limited by the capability of HTML.

The perspective that we're going to show you here is for HTML as a publishing medium. It's a ways to go from an SGML-based system or any other form of rich-source information and get that information out onto the Web; it is not in itself a repository format or an authoring format. But be careful, because what's happening all over the place, as we speak, is that people are authoring documents in HTML; and if you allow that to happen you are in effect building an HTML repository, and later on the only answer is going to be to say, “I'm going to have to put all this HTML stuff under control. I've got the ‘is this jive worth it’ version now, and I can't afford to sit and try to re-translate it back into Shakespeare.” And this applies at any scale. I'm talking about SGML and HTML here, but in between SGML and HTML might sit word processors or electronic publishing systems. Whatever the appropriate forum is for your source data, you should manage your own source data and look at HTML as the way that you'd get onto the Web, not the other way around.

SGML and HTML were meant for different things. We'll see this come out in the details that, as we look at this desire for simplicity versus wide range of needs, it's HTML that addressed the simplicity side of this. It's very simple. It's forgiving. It's basically meant to give you some presentation and some linking. That's what it's for and, like I said before, it's one-size-fits-all.

SGML addresses the wide range of requirements. It's extremely flexible and powerful. Its intent is to enable access and reuse, and it's application-specific. But, of course, in being application-specific, it gets complicated as well. We have to ask, what's wrong with simplicity?

Why not keep it simple? And one way to look at it is that in SGML, if you have a document — let's say this is something like a technical report — and it has Abstracts and Intros and Prefaces and Notes in it, in SGML I can make up objects that describe all of those things, and I put that into my DTD and I say, "Here's my application."

With HTML, which is bound to a particular set of objects when you get it out of the box, you have to decide, well, let's see, "Abstract." Is it a Heading? Is it a Link? Is it a Table? Well, the kind of the thing that's left is a Paragraph, so I guess an Abstract would have to be coded as a Paragraph in HTML. And actually, that's true for Intro and Preface and Note and Summary as well — they're all Paragraphs to *Mosaic*, if you will, so you've lost that distinction. And in losing that distinction you lose the ability to come up with a different format for presentation for each of those objects. That was very important to you when you were producing paper, but now it all kind of runs down the screen looking like a typical HTML document, because they're all Paragraphs and they all have the same style for that reason.

The same is true for search and reuse. I say I want to find *The Lion King* only if it's in the abstract. On HTML I have to say, "Well, all my effort is in a Paragraph and that means it could be many places. I can't localize it to the Abstract." That search point, which is often lost as people are looking for things like centering codes in HTML 3.0 and are really focused in on the format, is something that I think is going to be a more and more important part at looking at the Web, because the Web is the biggest thing that's happened to us since sliced bread. It is also the biggest example of an information explosion, or of the information explosion that we have in front of us.

I kind of look at it this way; in computer science we've been working efficient search techniques for a long time. First we had this sort of linear search, and that proved to be very inefficient — starting at the beginning and just going until you find something just doesn't work very well — so then people fairly quickly invented binary search. Now we're kind of going around like a pinball machine until we can find the thing in a little more efficient way, and people have been developing from there on and on and on. People get Ph.D. dissertations in more effective search rhythms.

With the Web we have brought ourselves to a new peak, or perhaps a regression, in the search technique that we use there, which I like to think of as "house fly" search. What do I mean by that? Well, have you ever noticed that when a fly buzzes around a room, it doesn't seem to have a very strong plan as to where it's going? It kind of goes zzzzzz...boom. And eventually, with that kind of search rhythm it will find what it wants. Browsing around on the Web, unless you're using a pretty highly-targeted index or have something else supplementing it, is a lot like the house fly searching for things; it's sort of fun if you like all of the scenery as you go by, but if you're really trying to get the right information to the right person at the right time, it's not a very efficient way to do that. Well, then why not use just SGML? [You might say], "You've convinced me, Eric. The heck with HTML, let's go with SGML."

Well, there are reasons not to do that, either. It's not quite that simple. There is, like it or not, a lot of up-front investment necessary to build SGML applications. The reason that it has been used on these very high-end systems, for the most part, is because they can justify that kind of cost up front because of what you need as the result. It takes a long time and it's fraught with difficulty with today's state of the art. And while I don't think that's so much a point against SGML intrinsically, it is a practical thing to remember that the state of the art right now doesn't really support just casual use of HTML with very little up-front investment.

Furthermore — and this is a little more subtle technical point which you'll see played out as you look at these actual DTDs and so forth with Diane — there is no standard backbone structure in SGML. There's nothing that pulls it all together so that everybody's talking the same language, because every application and every DTD is its own set of tags, objects, and

elements that somebody makes up for their own purposes. My application might call something a Chapter and an X-ref, and you probably can decode X-ref and say, "Is that like a cross-reference?" Another application is pretty obscure and cryptic: H1 and A. That's actually HTML. Maybe the H1 is fairly obvious because people are sort of used to hearing of typesetting macros named H1 and H2, but the A, what's that? It's for "Anchor Point," and it means a link. "Oh, anchor, I can see that." But it has to be explained to you. But HTML doesn't stop there; I could have tags that are called Joe and Schmo. They're just objects, and I get to name them. I get to tell you how they relate. There's no sharing of semantics between these applications that pull it all together into something like a WorldWide Web.

The semantics are in your head, and you're the one who has to know what they are. It turns out that I can explain to you that all the things in the top row are headings and all the things in the bottom row are links, and now you've got the decoder ring and you can figure out the applications. But with HTML, because you're bound to just the things in the middle, there's no problem like that. Every browser, every application can count on things being called the same.

SGML is powerful and flexible, but too general to really be the backbone as such. So how do we resolve this dilemma? How do you relate these two technologies to be both simple and powerful? Well, my assertion, and we're going to show you how this works out in detail in a moment, is to make it scaleable. There are a number of ways to look at this and a number of ways to implement it. The dust has not settled on this question yet, but one way or another we've got to look at this thing and make it scaleable.

The Web is about access for everyone, but the Web is going to have to handle much more complex material if it's really going to take off, at least in more serious applications than it can right now with HTML. Yet we don't want to make HTML any more difficult. So how do we do this? The answer has to be scalability, scaleable from simple applications to difficult applications, somehow all at the same time. And I would like to propose that the acid test for looking at the Web in terms of scalability is something like this: that you still need to be able to say something like "Hello, world" with typing a few tags in VI just like you can right now. Otherwise you've taken this nice, simple, generic thing and turned it into a monstrosity.

I want to be able to look at a corporate annual report or some other combination of highly graphical data, and yet do other data at the same time, and I want to do that on the Web. Maybe not in two to three tags, but I need to be able to do that also, otherwise this is doomed to be an interesting thing for home use and casual browsing but really not a business application. More than anything else I would like to be able to do, in theory, something reasonable with this data, even with the simplest HTML browser. In other words, no matter how complicated this corporate annual report is I'd like to be able to view it with *Mosaic* as it exists today, or something that's of that level of complexity. That, to me, is scalability.

Now, this is the kind of scalability we see all around us. We could just go home and watch TV because, as it turns out, I can go and pull a black-and-white TV set out of the attic of my grandfather's house — maybe it was built in 1960 or something or like, say, 35 years ago — and I can plug it in and I can watch today's stereo, surround-sound broadcast on that black-and-white TV. I don't get nearly the effect that somebody else does, but I can do it. I have access to it even with my very simple receiver. These days, of course, that's not how most people watch TV. If they have a big enough checkbook, they can go to the electronics store and they can add color, of course, and stereo these days, surround-sound, even things like secondary audio programs and close-captioning, all on the same signal.

But you don't have to do that. In order to receive today's TV programs, you do not have to go buy one of those sets; you can, in fact, strip all of that away and still watch it in black and white. You see, we could have said, "Now that the technology allows it, everyone must

have a home theater system.” But we didn’t do that. We didn’t restrict it that way. We also could have said, “Well, nobody gets anything but simple black-and-white because we want to keep it really generic.” But we didn’t do that, either. We allowed for black-and-white TVs and for TVs that can do all kinds of magical things, all out of the same signal. And that’s scalability.

Although that’s not a perfect metaphor for the Web, that needs to inform how we look at these standards and how we put together the systems using them. It is possible to look at HTML and scale that in somewhat the same way by looking at these objects like H1 and Paragraph and so forth as actually being classes of objects for which the user might have more specific distinctions — like Abstract and Note and Paragraph, all of which turn out to be related to the higher-level class of Paragraph.

In the current proposal for HTML 3.0 there is an attribute in there, as Diane will show you, called Class, which is meant to be able to capture some of that side-band signal with the surround-sound in it, if you will. But for a simple browser, you can collapse it all back down and say, “I don’t understand about Abstracts and Notes and Summaries and what to do with them, but I do understand Paragraphs just like I could today.” That’s just a basic construct in HTML, but now I’m looking at it as a class of object. That allows you to take an HTML browser, which looks at a document like this, and have it actually look at rich source data with all of those distinctions explicit. By overlaying through this concept of “my user-defined objects actually fit into these classes of HTML objects,” I’m able to look at it simultaneously as black and white, if you will — or, if I have the right receiver, as stereo surround-sound and color. And this works with any kind of SGML document.

I could have another one, like this as a magazine article with Abstracts and Headlines and Bylines and Sidebars and that sort of thing. I’m limited to the same set of classes from an HTML standpoint, but if I overlay that on this, I again have this ability to look at it in black and white or in color and stereo.

There are a number of different ways that this kind of technique might be implemented, but the key point to begin with here, to inform what we’ll talk about in a moment when you look at the actual tags and attributes that are underlying this, is that if you don’t think of this as a scalability problem as developers, you end up creating two separate worlds. However this is implemented inside the standards when the dust settles, if you think of it as a scalability problem then you are informing the way that you’re putting together these systems, so that in effect you can achieve this access for everybody with a backbone structure and yet not giving up the richness of the source data.

So HTML and SGML need to coexist on the Web along with some other formats but, as I’m saying, with smooth scalability so that there’s a way to start out using simple things in HTML but also be able to express more complex data using the same basic architecture rather than creating a quantum leap where you’re either in the HTML world or you’ve made the jump into the SGML world. HTML is about open access for everybody; SGML is about application-specific access, and it doesn’t have the backbone structure unless you put something like HTML as a wrapper around the whole thing, at least conceptually, to allow everyone to understand each other’s data at least at the level of, let’s say, a black-and-white TV signal.

So, for this overview and perspective part of the tutorial, I would summarize it this way: HTML is an SGML application. It’s not in competition with SGML, technically because it already is SGML, but it’s a specific binding of SGML for a very specific purpose. It is not meant to be something that is the be-all and end-all of everyone’s need for data storage. By looking at it as a backbone, it is possible to both take advantage of SGML’s power that underlies HTML and use the simplicity of HTML as an organizing principal for how we’re distributing information, without having to throw away the source data that underlies this if you look at HTML as the delivery mechanism to get to the Web, not as the core of your system.

So, for this part of it, thank you very much. What we're going to do now is take a stretching sort of break here, and when we come back we're going to start with Diane. We're going to go down into the hands-on level and really get to the sort of nitty-gritty part of the tutorial here. So, we'll see you in five minutes.

[Tape change]

Diane Sandstrum: Okay, I think we'll go ahead and get started again. Can everybody hear me okay? I would like to introduce myself. My name is Diane Sandstrum, and I am a regional Training Manager for Interleaf. I oversee a lot of the SGML course development relating to SGML and our products, the related technologies that we have to deal with these conversions and what-not.

What I would like to do is I would like to expand upon some of the things that Eric has brought up and proposed and take everything sort of another level deeper to take a look at some of the technical aspects that underlie some of these ideas that he has presented.

What we'll do first is go over some HTML basics, some of the raw technical stuff that can get really dry at times. We'll try to cover that pretty quickly, but I think it's very important to go through those so that you can have a deeper understanding of some of these issues that Eric has brought to the table. Once we go through those SGML basics, then we'll be able to take a look at how HTML really does fit into SGML. We'll take a look at some of the features and functions that HTML is or isn't, and then we'll discuss a little more how HTML could evolve even further with SGML.

Some goals that I have: I would like for you to leave here today with a pretty good understanding of SGML so that you could pick up a DTD and casually read through it. We're not going to go through all the details of the DTD; I don't think anyone is really that interested in going into that kind of detail today. But hopefully you'll be able to get a good general idea of what's going on in these DTDs.

I would also like to link back to some of Eric's concepts that he brought up with some more technical examples, so let's flip back for a second to some of the things that Eric said.

He pointed out that SGML is really about objects that we can define. We decide what objects are important to us to take care of in our documents, but it's more than that. It's really SGML that homes in on the structure of those objects that we're managing, and that's done through the DTD. The DTD is a specific application of SGML, including HTML.

I think what we should do now is look closer at what these objects are, what the structure means, how we define the structure between the objects, and what these DTDs are. What are these all really about? What goes into a DTD? It is your Document Type Definition; you are basically defining a type of document that you may have out there. You pick out the specific elements that are important to you to control and, more importantly, you are defining the relationships between those different elements.

What is the structure that's defined within that document that you have within your document? You have chapters, and within those chapters you have sections. Within those sections you get into more the detail of your document.

What about formatting? Where does that fit in? Well, Eric had pointed out that we're really getting away from that, and we want to be able to not concentrate on what something looks like or how it's presented. But really, on what part of the document is this and how does it relate to everything else around it? Formatting really is not a part of the DTD. We're just focusing in on the elements and their structure.

What does the DTD look like? How many of you have seen a DTD before? Okay, a good number of you. This is a very simple, small snippet of a DTD. We'll kind of focus on some

of the details here, some of the syntax so that you can understand or have a better appreciation for what's really going on in this simple text document. Here is a sample of some HTML mark-up. Eric showed us some small snippets before.

Basically, all we have is a document with some mark-up in it. And by mark-up I really just mean additional information that we're putting into the document to enrich that data. This happened to be some tags stating what types of elements we have within the document, and we'll take a closer look at this also. I would like to point out, though, that each HTML mark-up, as I'm sure most of you have seen, absolutely looks at the [inaudible] documents. It is the same; it's HTML mark-up, but it just has a specific set of tags that it is using.

Let's delve deeper now into the jungle, or under the hood of it, to look at these different components of the DTDs, focusing in on the main things that you will find: your "elements," your "attributes," and your "entities." So back to that sample DTD that we looked at; we'll look at these element declarations or attribute declarations and entities, how and why they're used, and how to get the most use out of them and so on.

Let's start with elements. Again, we're just identifying specific pieces of information in our document. Now, each element that you have and you define in your document contains many different things. It could contain other elements like a chapter, it could contain a section and so on, it could contain actual data or it could contain a combination of the two. So take a look at that.

Here's a sample piece of mark-up. I just want to point out, in reading the actual tag SGML files, that what we have here to identify each element is a set of tags, both the begin tag and an end tag. It's simply the name of the element with angle brackets surrounding it to denote where that begins and ends. The end tag is just like the begin tag, but it does have the forward slash at the beginning of that tag to denote this is the end of this element. And I've just highlighted in this mark-up all the tags for this simple example.

More importantly, what's going on here is that we can actually see a structure unfold here. If we walk through this, we can see within our Chapter element — our Chapter contains what? A Title and a Paragraph. It begins and ends here and then our Chapter ends here at the bottom. Our Title element has what? Data. But then if we look at our Paragraph element, we have Data and nested within that we have another element. Those are those three different options that you have, or ways to define an element and the types of information that it can contain.

How you actually define an element in your DTD is pretty simple. We're going to name it and then say what types of things it can contain. Now, this is actual syntax you see in the DTD. For each thing that you define, you'll see the set of angle brackets as a line item in your DTD. So we see here that we have the angle brackets surrounding our entire definition. You'll see an exclamation point, which is just saying I'm going to define something, and then what it is you're going to define. In this case it's going to be an element, and we're going to name that element, and then following that we have our content model.

I want to talk about this content model. Again, we have three options of what an element could contain. It could contain other elements. Our elemented Chapter contained what? A Title and Paragraph. Our element of Title had just Data and that's listed here. It's denoted with a pound sign, PC Data. It's just a specific type of data that's available to you, and has special meaning in SGML; but if you see anything in your DTD that says "data" in it, it's raw data [such as] S-Data, End Data, C-Data, PC Data. We don't need to get into the detail of how those distinguish from each other, but just so you know if you come across it, you'll have an idea of what it is.

Here we have an example of how an element can contain multiple combinations of things. In this case our Paragraph element contained Data and an [inaudible] element for

emphasis and so on. Here's our small DTD for our small mark-up example that we had, and I'd like to just pull up that mark-up with it and just walk through and show you the different pieces, and exactly what we're defining. I'll highlight as I go through what's being defined and where that sits in the mark-up.

First we have our Chapter element that contains this entire block here. The chapter contains a Title and also a Paragraph. Our Title has just the Data, PC Data, raw data here. The Paragraph begins and ends here, and has Data as well as that nested element; and then we go down to the [inaudible] and that contains just Data. [So that's a] simple walk-through of our DTD and our mark-up.

What I'd like to do is point out a couple of things. How we are actually defining structure and order? Those are very simple examples, but you can get into much more complex structures, and there are some different notations that are used to help you do that. I would like to go over these in detail, and how they're used and how they can help you define the relationships between objects — sort of the when and the where of the things that will occur in your documents, whether some things are required, how many times an object can occur, and what the order is that these things should occur in.

There are two different types of notations that you can use: those that help you define the order of elements and those that help you define the occurrence of elements. We'll start with the order. We have these three different "markers," I guess you could say, that help you define these relationships: your comma, the [inaudible] bar and the ampersand. When using a comma within a content model, you're saying that these items, as I list them, must occur in this order. Here we have an element called Letter that has an opening followed by a bobby followed by a closing. Those are all required and they must be in that order. You can't have your closing first, per se. Then we have the [inaudible] bar. This lets you create a set of conditions where you're basically going to pick one of these options.

For my List element, my List element is going to contain either bulleted items or numbered items, one or the other but not both. And then the last for ordering is the ampersand, and this says that all the elements within this list or set must occur, but they can go in any order. A good example of that is a Memo; a Memo contains these items: it has a "to," a "from" and a "date." All those items must be there but I don't care the order that they come in, so the ampersand is used to separate those. Then those three items, in whatever order they come in, are then followed by a [inaudible]. Okay? Yes.

M: One question: [inaudible].

Diane Sandstrum: Yes, and that's actually — you caught me. That's a mistake. I have an unmatched parenthesis; sorry about that. Good catch.

Going on to some other notations that you can use... These help you define whether or not something's required or not, or how often something can occur. We have three indicators here: a question mark, an asterisk and a plus sign. How the question mark works is very simple; this, when following an element or set of objects, means that that is optional. It doesn't have to be there but it can. So you'll see that in your document either zero [times] or one time.

The asterisk is similar to the question mark in that the element that precedes it will be optional, but it also allows it to repeat. So you'll see something with an asterisk on it zero or more times. It doesn't have to be there, and if it is I can have as many as I want.

And then, similar to [the asterisk] in that it's repeatable, is the plus sign. It allows this item to repeat, but it's also required. You must have it at least one time, but you may have it as many times as you need.

Let's just look at these examples here. We have an element called Manual, and it has a Title — followed by what? One or more Chapters, and then an Index, or maybe not [an index], it doesn't matter. Then we go into this Para One element, [with "Para" being short for Paragraph]. This has an Optional Title followed by a Para, and then down here we have a set of items that have a question mark on it — so this whole set within the parentheses is optional. But if we do have that item there, what is it? It is a Subpara — followed by what? One or more Subparas, meaning we must have two or more. So there are no indicators that say this has to occur three times, but you can explicitly define it.

A [inaudible] is one followed by another followed by one or more. And then we have down here — we're going to have a dinner order here, and our first item is an appetizer and that's optional but repeatable, so you can have as many appetizers as you want. That's the one that my husband likes the best. You may pass on the soup, but you're definitely going to have an entree and then one or more desserts. That's the one that I like; you must have dessert, that's the best part. You cannot pass up on dessert.

W: But you can pass up on appetizers.

Diane Sandstrum: Yes. And soup. But multiple appetizers, you can order them all.

I think the most important things that you want to look at when you first are looking at a DTD are: understanding how to read these content models, [understanding] what all these little symbols mean in between, and what it means for the structure of my documents. And these help you to, again, say how many times something occurs, whether or not it's required and where it sits in the order of the whole scheme of the documents.

In defining instrumental elements, you can — or I guess if you look at it, it's how can I use my SGML elements to their full potential? What can I get out of them? Well, you can create a whole wide variety of elements. If you're setting up your own DTD in your own SGML application you get to define what it is that you need, and that variety of elements that you can lay out can be very beneficial to you in that you can create very robust documents either for use now or for reuse later.

By having a wide variety of elements, it can also help you with search and retrieval. We'll take a look at that, and Eric could mention that also. And with this structure here you're defining the structure, and that structure will be validated, and that can be a very important part of the process. Eric talked about this idea of how SGML allows you to have many different objects — versus HTML where you're limited at the Paragraph level to really just one object — and how that can help you because you can apply these different styles to distinguish those different elements, and also to help you in your search and reuse. So I'd like to expand on that a little bit more.

Let's say we have sort of a one-element structure. We have an element of Body that contains — what? One or more Paragraphs, and that Para has our Data in it. If we look at the structure like that versus something where we have a more robust element structure, where we have our Body that contains a Para, Note, Warning, Abstract [inaudible] — and you could go on and on — and all of those different unique elements contain Data. We have a much richer base that we're working from.

If we were to just display a document to see what that document would look like — I've set this up. It's not important for you to look at the content; it's a little blurry for you. But what is important is for you to just [look at] what catches your eye, which formats are catching your eye. The actual content of both these documents is the same, but the Abstracts, the Introduction, the Note, the Warning and the Summary have all been formatted differently. But if you're going with an HTML type of distribution, you're really limited to one Paragraph.

And now to research and retrieval... Here we have Mr. Supervisor up in the corner telling Joe Worker here to go and gather all of the Abstracts. He's completely baffled because he's looking at his HTML, his whole suite of HTML documents, and all he has are Paragraphs. He doesn't know what to do. We have this other worker over here who's very happy and very excited because it's very easy for him to go and extract that information, because it's been explicitly encoded in the file. So that's how having the variety of elements can help you.

Let's look a little bit more at the document structure and what that's all about. In the content models you can define these explicit structures within your document and create these different hierarchies. You may ask why that's important.

The thing about using your SGML documents is that when you go to process the SGML, the first step in processing the document is the document will be verified or [inaudible]. And what happens in that stage is that your document, with all of its tags and mark-up, is checked against the rules that have been defined in the DTD to make sure that everything is in place that should be there, that nothing is out of order and so on. That can be very important, whether it be for a standard or for your own use of information. It may be absolutely crucial that that be there, and without having to do a manual check to see that that's there, you can have a much more automated process for that verification. Also, it just helps to maintain the document integrity for now and for reuse later.

This might be a little extreme, but the whole point here... Here's another supervisor. He's very angry at his employee because somehow, when these documents went to print, those Warning Paragraphs got left out. Now this guy's job is on the line, and he's sweating a bit. Again, it's probably not a realistic example, but the whole point is that the SGML can help you to verify the structure of your documents and verify what's required and what needs to be there.

By using a robust set of SGML elements you can have a more focused search and retrieval and you can get into more component-level management in maintaining the information, more of a granular level. Rather than an entire document or entire chapter, you might want to focus in on specific sections and so on. You can validate the structure, you have more flexible reuse and your documents are much more rich and robust.

So that's about all I'll say right now about SGML elements. Once we get through some of these SGML basics, we'll refer everything back to looking at HTML and what it all really means.

Do most of you know about attributes? No? Yes? Basically, an attribute is an additional piece of information that's carried with an element. If you look in the mark-up where you see these attributes occur, [you'll see that] it's in the start tag for that element. See, here in our Chapter we have an idea of CHI, [which is] just an ID that's attached to that. On our Emphasis element down here we have a Type attribute, and this one has a value of "I". What type of emphasis is this? In this case it might mean italic and so on; it's additional information that is carried with the element, whether that element be your highest level element of the document or something [else]. It's small down here as one of the characters in the paragraph.

How you define attributes in the DTD is like this: this line might look somewhat familiar to how we defined our elements; we have the angle brackets enclosing the entire declaration and we have our exclamation point, and what we're defining here is an attribute list. What we do is we give the name of the element that this attribute refers to, or is attached to, and then we name the attribute and give it a valid value or set of values.

Looking back at that simple mark-up that we just had — where we had the Chapter and Emphasis both with attributes on them — we have our Chapter here. We have an attribute list for our element Chapter; the attribute name is "ID." What does it contain? Some Data. Then, down here on our Emphasis element, we have an attribute list defined for [inaudible]. We've

named it "Type." What are the values that you'll find there? Well, here we've defined an explicit list, and you will either see a value of B, I or U as a value for that type attribute.

How attributes are used is a little bit more interesting. There are sort of some general, generic uses of them and then there are some more interesting ones that we'll look at also. In a generic sense or general sense you can see attributes used to carry just additional information about that element. And here we have, say, our Emphasis type as italic. We're just implying generic formatting.

Again, with SGML we are trying to get away from holding on to that formatting information; but in some cases, if something's been emphasized, it's important to hold on to that because you don't want to lose the fact that there was something special about it. Say, for a picture, you want to just store the dimensions of that particular graphic. You can do that. You can define a height and a width attribute to store that information. What we see commonly used, even in HTML, are external file references, and in this instance what we have is a graphic defined, and we're going to just specify where that graphic occurs. And with our SGML, again, we're dealing with just text; we can't store the graphic information in the file. We just link to it, so we have a pointer out to that file. So these are sort of general uses, just additional information that can be carried with those elements.

[There are also] some more uses of attributes that I think are a little more interesting, and you can get into some more Abstract ideas rather than the concrete measurements, say, that we had on the pictures and the examples before. With attributes you can include information in your documents that really can't be stored anywhere else, such as these Abstract concepts of, you know, what's the status of this document? What's the security level of this paragraph? What user level should be reading and accessing this information? And this can be really, really useful.

Say we happen to store all this information in our document at all different levels. We have Top Secret, Classified, and Unclassified as well as Beginning, Intermediate and Advanced-User levels, and we store it all in one document. What we can do is go out and automatically assemble a book or a new manual or a new chapter that specifically fits the needs of those people at the advanced level that have, say, top secret clearance. And it's that type of information that you can use and store in your documents that really makes using these attributes much more interesting rather than explicit and concrete information. You can get more into these Abstract ideas.

Another thing that you see widely used is this idea of a cross-reference. I kept this under the Abstract idea because you're really building a relationship between these two items. How we see this come out in our browsers or our viewers are hyperlinks, or hotlinks or hotspots, whatever you call them. You have a point in a document where you're referencing something else; well, there's a unique relationship between those two points in the document. How that's represented in the SGML is through attributes where we have, at the reference point, an ID attached. In this case, at some point in the documents I've said, "See Table V." I have a rough idea of Table V, and then later on that Table I have the same idea attached to it. That's what's creating that unique link and allowing you to bounce and hotlink through your documents.

So attributes really add a lot of value to our documents. Again, you can store this more abstract information about the different pieces of information, and we could even go further and help us to use the attributes in our search and retrieval. Maybe we don't have the explicitness at the element level, but we could possibly use attributes to help us do that. Or, just in reusing that information or applying formatting at a later time, we could maybe look at the attribute level to help us decide what to do with that.

We have one more topic to cover on the SGML level, and that's the area of "entities." This one I'll do fairly quickly. An entity is basically a unit that's defined that represents something else. That something else really can be anything; you can define an entity that represents a special character like a Bullet, an Omega — something that you can't represent as text in your document. It can also represent just a simple string of characters, just be used as a simple string replacement or for an external file reference. You see entities used both in the DTD and in your mark-up, and we'll look at an example of each of those and how they're defined in the DTD. Again, we see this similar syntax. What we're defining here is an entity; we name that entity, and then following it is what that represents. It's pretty simple.

Here we have an entity that we're defining in our DTD. We're calling that entity SGML, and what that represents is the "Standard Generalized Mark-up Language." Then later in our mark-up, on our [inaudible], we have a Paragraph. We're going along, and instead of typing out "Standard Generalized Mark-up Language," we just make reference to this entity by using the ampersand followed by the entity name followed by a semicolon. That is actually, at that point in the document, referring to this string up here. Okay?

That's one example of how you could use entities in your mark-up. We'll look at how you use them in the DTD. This, again, is just a simple string replacement. What we're doing is we're defining an entity called "Paras," and the type of Paras that we have are Para, Note and Warning. Later — say we're within our section or subsection or third level section — we want to have the ability to reuse that information over and over, and we simply make a reference to that entity. So here we have an element section that contains a Title followed by Paras, and that could be any one of these. It just does a simple replacement. By using entities you can really gain a lot of flexibility. You can get away from having to do a lot of replacements globally in your files; if you need to change a phrase or a term or what-not, you can do it locally just in one location where that entity is defined rather than throughout all your files. It can also help you to build a framework within your document structures.

Say, in that last example, that we defined a set of Paragraphs that could occur at many different levels in the document. Well, say we want to add a new type rather than going to all of those different declarations that would reference that; we would just have to change at the entity declaration level what types of Paragraphs we may have. If we want to add a Summary Paragraph it would be a very simple addition. It also helps you with consistency; you're always sure a specific item or phrase is represented properly.

You may be asking, "Now, what about HTML? Enough about all that detail — let's get down and let's look at how this really related to our HTML." What I'd like to do, based on what we have just learned about the elements, attributes and entities, is take a look at the HTML DTD and walk through some of it so that you can feel pretty comfortable reading through it and understand what is actually going on there, and see what features HTML does and doesn't use. In that hand-out, the back two pages, I've actually included excerpts of the HTML DTD so we can walk through some of this together.

I will note first that this is not the entire DTD. What I did, as I said, was get rid of a lot of the stuff. For discussion purposes we don't need to look at everything; we want to look at the main structure, the main elements that are being used, and kind of clean some things up to make it easier to read. So this has been modified and I've noted that on your document.

At the very highest level of our document structure for HTML, we have an element called HTML. That's something I didn't mention that I do want to point out. What are these characters following? Our element names? We have a bunch of "O's" here, and this is an optional feature of HTML that allows you to minimize the number of tags you're using in your mark-up. In this case, or for this application, this optional feature is being used and we've

specified for the HTML highest-level element our Begin and our End tags are both optional. If you were to see a dash in place of that...

[Tape change]

Diane Sandstrum: ...back in position is required. So it just kind of cuts down on the number of tags you actually have to have in your document. So, going on, let's look at the content of our HTML element. What do we have over here? It looks like an HD reference, which is using that percent sign followed by the entity name. That entity is sitting down here. HTML content contains what? Head and Body. So let's look at Head and Body.

Head contains Head Content, Body contains Body Content — we're not getting anywhere very quickly here. You'll find as you go through this that a lot of entities are used, and you always have to find — once it's been referenced you have to go and find what that really means. So let's flip; I'm actually going to flip to *Word* so we can browse through this a little bit more.

So, where were we? We found out that HTML contains a Head and a Body, [and we were] looking at the Head and the Body elements and their entity declarations for their elements. We have a Head Content reference, and down here I have listed most of the entities that we'll be discussing all in one section. Head Content contains what? A Title and then IS, index-based, and the next ID, [which is] some indexing information that we really don't need to be concerned about right now. The main thing that we're looking at here is the Head Content that contains a Title; then we go look at our Body element here. Our Body element contains this Body Content entity. Well, what does that represent? Here it's a long list, and a number of other entity references are being made.

I did a little homework for you and I summarized most of the main elements that are actually being referenced, [the ones] that you see used and you mark-up often through these different entity references. The Heading entity reference represents this list of Heading elements, H1 through H6. So you can have six different types of headings, followed by syntax elements and Paragraphs. Looking down here at a Paragraph element [we see] an "OL" and a "UL," which is actually used for an Ordered List or an Unordered List.

And then we get down to a Data level of elements, things like PC Data — which we saw before, which is just your data in your document — and then things like "BIM strong." Those are all the emphasis tags that are placed to indicate the emphasis, things like A which is your Anchor, your linking reference. We'll take a look at some of these a little more.

[Next we have] Images and Line Breaks. There is a lot more that actually can be contained in there. I didn't list them all, but just sort of the main ones that you really see used. One thing I would like to point out, though; here, at this level, is really where we're getting into the gut of our document. We have Headings intermixed with Paragraphs intermixed with Data intermixed with Anchors intermixed with Emphasis — I mean, it's really just sort of a random — everything is separated and used using this [inaudible] bar to separate it, so it's any of these things in any order and there's no real structure that we're getting out here. Once we get to the bulk of this DTD there's a lot of possibilities, but there's no structure. It's really a free-flowing, free-for-all structure.

Here's just the rest of these entities that were referenced up here: the Heading and the Text, where I pulled some of this information from. Let's look at our Paragraph elements. What do we have? We have one Paragraph element called "P," and that contains our different text options that we have. Just to refer back to our Text entity reference, our Text entity is defined here as PC Data, an Anchor, an Image, a Break, some Phrases and Fonts — and it expands further.

At the Heading level we've defined all of the Heading elements to contain the same type of text. We're actually using — this is something a little different, the entity reference to define all of the elements. So they're all being defined.

Here's our Lists, and I've taken some of the stuff out of here. There's some more attributes and some things on them that weren't that interesting for discussion right now that have moved to a different place; but the Unordered List and Ordered List just contained List items and so on.

Here's our link mark-up. If we go down a little more to element A, it contains some content which is either a Heading element or a Text element. So the Anchors can contain Headings, the Headings can contain Anchors — there's no control in place there at all. It's just sort of... It can spin off and next there's no control structure at all. But within the Anchor element it's using a number of different attributes to carry the information about the link. And there's attributes that are defined below here.

What's more interesting, though, is showing how they're used. It's a little easier to read up here: the name of the reference, what this Anchor point is or what the element is that's being referenced somewhere else. The "A" tag is used both as the Anchor and as the Reference point, just depending on the attribute that you use, whether it's considered a reference or an anchor. I should also point out that in the DTD you see these within angle brackets: an exclamation point, dash-dash, and then towards the end, over here, before the close of the tag, another dash-dash. That just denotes a comment, so it's ignored by your [inaudible] or your processor.

That's really about it. At this point I want to cover the images, and how the graphics are represented. It's a place folder; you have an imaged tag, and then a reference made to the file where that graphic sits, and as far as the main elements that you really see and use, that's about it. At the highest level of the document you have this free-flowing structure going on where there's no control of where anything goes.

Does anyone have any questions about that?

W: [inaudible]

Diane Sandstrum: Sure, sure. Let me — actually, that's a good example. It's better to show you in here because we'll see an example being used and not used. Okay, I should have turned off the [inaudible]... Characters are showing up as a dot right now, so just ignore this; but this is this "tag minimization" feature, and what this allows you to do is specify for any element whether or not the Begin tag or the End tag are required or optional. How that's represented in your declaration is [like this]: following the name of your element you have two slots, basically a slot for the Begin tag specification and for the End tag. Using an "O" means that it's optional.

So we could have an HTML mark-up instance that never has the tags "HTML" at the beginning and end. They're both optional. But when we get down here we bypass the Head, we bypass the Body and we get to our Title. The Title has a dash instead, so you have to have a Begin and an End tag for that element.

M: If my understanding is correct, [inaudible].

Diane Sandstrum: Okay. What this is — I pulled it up in Word only because I wanted to be able to bold some of the items, that's the only reason — this is a pure text document, and all DTDs are just pure [inaudible] documents. Within them you're defining elements in the structure. And I just chose to display this [inaudible] document in Word.

M: [inaudible]

Diane Sandstrum: They never actually have to send — right, because that's assumed that you're using that HTML tag set. The browsers have the knowledge of the HTML DTD basically built in.

M: [inaudible]

Diane Sandstrum: Actually, at the Paragraph level you have to have a Start tag. Many times you see the End tags left off. Something that's interesting, though, about the optional tags is that you can get into a mess very quickly if you don't use it properly, because it's very sensitive to the context that you're in. If you say that something is optional, really the only place that you can do that is where there's no question about what that element is going to be. You get to a Title; well, that means that if I'm in a Title, I have to be in an HTML document and a Heading. So I don't need those tags; that's just assumed because that's the only place that item occurs.

W: [inaudible]

Diane Sandstrum: It might. It might depend on the browser, on how the browser interprets that. Some might not allow for some of the features, and there is not — there's a common ground. There's a common set of tags that are being used here, but there's not necessarily common applications of that being enforced.

M: [inaudible]

Diane Sandstrum: Right, there's definitely subtleties made, sometimes subtleties and sometimes major differences between the different tools and how they interpret the information that's there.

Okay. Before I close up, does anyone else have any questions about the syntax here, or do you feel pretty comfortable kind of traipsing your way, getting a feeling for what's going on? We're not going over everything in here; we could spend days in here learning about this if you really want to, but I don't think you do, at least not at this point.

So, okay, we've looked at some of the basics, and looked at the HTML DTD. Let's see what features HTML is actually using and what it's not doing. [What it] does do really well are cross-reference links; that's really what a lot of the excitement is about, that we can link to all these other locations and all these other places very easily using those attributes and the information that's stored in them to create the unique relationships between the different places of the link. It also makes use of external file references for graphics images and many other items that you can pull in. And entities [are linked] to a certain extent, mainly within the DTD, but I don't necessarily think that I even agree with how many of the entities are defined and used.

In my opinion you usually define an entity to use in the DTD because you're going to be referencing that in many locations. A lot of times what you find in HTML DTD is that it's just defined and used in one place and it's not an effective use; but it is kind of going towards developing that framework. So if you did need to build off of that, you have some references that you can make.

M: Excuse me. Is there a fixed set of [inaudible]?

Diane Sandstrum: I think that the HTML DTD actually references one or a few of the ISO character sets.

M: Did you take any of them out of here?

Diane Sandstrum: I didn't take anything else out. This is an HTML 2 DTD of what's accepted right now. I don't know what's being proposed; I think maybe HTML 3 has more. I'd have to pull it out and take a look at it. But what HTML does do really well is that it's providing us a backbone. It's giving us, in the sense of an SGML application, a common backbone that we can all build our documents off of. We're all using the same set of tags and — granted, there's not much structure there — but we're all at least using the same tags, and that's a good thing.

What HTML doesn't do is define any kind of hierarchy, and we'll take a look at that. It's a very flat structure that we just saw; in fact, there's no enforced structure at all, really. Anything can go anywhere in the document, where nothing is really required with the exception of the Title element. That's the only thing in your document that is required. It could be an empty Title, but those tags at least have to be there. And there's really little variety of elements other than at the Heading level.

We do have six levels of Headings that we can use, which is pretty good, but outside of that we're really limited. You get into the content of your document and everything's thrown into that "P" category, that Paragraph category, and there's no variety or distinction made there and it's not making use of attributes to be able to pass along this more abstract information in your documents. So it does a lot of things really well, and in my opinion it falls short in some places where there could be some more there to give us some more functionality and make some more features available to us.

[How do you build] SGML hierarchy? We can go wild, actually. You can build hierarchies as complex and strict as you need them to be — or you don't have to. Your hierarchies that you build and the rules that you set up don't have to be necessarily that strict, but they can be if you need them to be.

Here's a look at what a complex HTML hierarchy could look like, and the interdependencies and relationships between the elements. This is what our HTML hierarchy looks like. I wouldn't really even call it a hierarchy; I mean, we have HTML Head, Body, here's our required Title and now here we just have a swimming pool of elements. There's really just a free-flowing lack of structure going on out there.

Looking forward, we'll kind of look at the question again that Eric posed: Why not use SGML on the Web? Why is that not a very good option? And the other possibility: How can HTML evolve with SGML? We'll talk about some of the things that are proposed in the HTML 3 DTD. And why wouldn't we want to use SGML on the Web?

There are some tools out now, things like *[Panorama] Pro* that allow you to read and view your SGML documents, but there's still some set-up that's required there because you don't know what set of tags are going to be coming in or what the DTD is for you to create an environment where you can view that acceptably. Then there is some work involved for each specific application there.

A better approach, as Eric proposed, could be this: if you need to use SGML, then that can be more the center of your repository and HTML can just be one of the forms that you publish that information in. Another thing that can be explored is empowering HTML a bit more to use some more of the features that are available to it with SGML, such as maybe not making it as strict as some SGML applications that are out there. We don't want to go that far, but maybe we could come up with some kind of balance between the two where we get some more of the features and not necessarily make it too strict or enforced.

What Eric proposed is that we're leaving HTML as a backbone structure but utilizing more of the power of SGML. Many of the features can be optional and only used if you choose to use them. He used the example of the TV signal, with the color, surround-sound, home theater system compared to your small black-and-white TV that you might have. And what does this really mean for HTML if we try to pursue this route? What we would need is a reasonable framework for searching and linking, but with no real structural constraints placed upon your documents or defined in the DTD. We want very few required [inaudible] if we want to meet Eric's acid test of being able to put out a statement of "Hello, world" without having a whole suite of tags in place to mark this defined structure. We can use a simple tag set, but then we have some optional classifications allowed for those users to want to develop a more sophisticated occupation.

So we might have something on the structure side in setting up the relationships between the elements where you have a very simple and flexible structure, where you might have one structure defined that could be accessed at many different optional levels versus something that's really tight and rigid. Make it a little softer on the outside and make some of these other features optional.

Making a reference back to the black-and-white TV signal that everybody can understand and that would be compared to our base level HTML — anybody can read it, but then for those people who have more advanced systems and care to delve into this, they may have some added richness to allow them to access the color, stereo or close-captioning, or on the HTML side things like tables, equations or user-defined objects.

This could be done possibly — well, we talked about the riches that you can get from defining the different types of elements either through your element classifications or the possibility of doing that through attribute specifications. So let's say that we have our "P," the Paragraph element of class; the default we could define as Para and then we could have all these user-defined classifications that we may choose to use, but it doesn't matter if we don't. And if someone is reading our document that doesn't choose to go into that richness, they would see everything as a standard paragraph.

I'd like to just point out some of the things that are in the HTML to read, [some things] that have been proposed, and kind of the direction it looks like things are going. Actually, the documents with this DTD can be more robust in many different ways. They've added a class attribute, and we'll talk about that. They've added the ability or proposed the ability for tables in math which we didn't have before. If you had a table structure, in your HTML 2 you're forced to format it and make it look — you know, with tabs and spaces and what-not so it looks something like a table, but you've lost all the integrity of that structure there. That's allowing for text flow around figures and tables so that you can get more complex published documents.

There are more element types even at the Paragraph level; there are some things like a Note or things like Warning, I believe, that are creeping up that give you a little more variety at that level, but maybe not as much as you may need for your specific application in your documents.

Let's look at this class attribute. I believe it came straight from this proposal that Eric made that we be able to, at the element level, give the users the ability to specify what type of element or subclass this is. So we may be able to take a Paragraph or "P" element and classify it as an Intro, Abstract, Summary or Preface.

This has actually brought up some kind of controversy around this, because people have said, "Well, what if we want to take this even farther? What does, say, an Abstract mean? Is that necessarily an Abstract that occurs at the Intro part of the document or do you have an Abstract somewhere else? Can you specify the context that those elements sit in?" And it gets into this debate between getting into structure or focusing on just the element types. I don't

think that there is a clear answer for this; they've talked about, actually, within this class attribute, using periods to separate elements so that you could specify a context, so you might have a section-dot-title or a subsection-dot-title so that you can make a distinction between them.

This, I think, is still probably much up for debate as to what the proper usage of this particular attribute is, but the idea that it's theirs is actually very exciting, that we can possibly use this to our benefit to help further define the elements in our document. And even if we don't get to the structure level, to where we're saying, "this is the Title within the Heading," or, "I'm sorry, within the Section or the Subsection or Sub-subsection," just the fact that we know that it's a Title is very powerful, or [just knowing] what type of Paragraph it might be.

A couple of other things that are happening in the HTML 3 proposal are some more formatting-type features. I've got some mixed feelings about some of these. There's something called the Style attribute which allows you, as I understand it, to specify how this should be formatted or how it should be presented in the viewer that you're using. There are overrides that are available, but you're basically trying to control how this information is going to be viewed by the end-user.

M: Is this style [inaudible]?

Diane Sandstrum: That's a good question. I actually haven't made use of that particular attribute myself. As I understand it, it's more carrying the Style information, how it should be displayed by the browser. I don't think it's actually referring to an external [inaudible] because it's more element-specific than document-specific, as I understand it.

M: My understanding is that [inaudible].

Eric Severson: Yeah, this is the same thing. The discussions have included things having the stylesheet imbedded, kind of giving a hint so that if you can recognize something like Bold in the browser, you'd say, "Got it, I'll implement my notion of Bold." So far as I know, those things are not settled yet, but this is the idea.

Diane Sandstrum: There's also an Alignment specification that can be made where you're specifying this should be centered left to right or justified, where you can basically put a permanent header on your document and things like information about the space that's required on the page for a particular type of element. Some of this information, I think, is very useful because it's really getting more at how to publish this information effectively. Some of it, though, may be kind of pulling or pushing us away from a more flexible system and forcing us into allowing people to control the formatting and include that formatting information with the documents, when we're trying, in a higher sense, to really get at what the key components of this document are. Then the formatting of that falls into place and can come later.

It's just sort of something to think about, what kinds of controls — some people will find that they want to have that control. They want "This is going to be centered, I want that control." But it's just sort of weighing what's important about the information.

Some of the questions that Eric posed earlier that are commonly asked, again, are, if you have HTML, is there any need for SGML and can HTML be used as a center change format? Can I store all my documents in this format? And I hope that through Eric's discussion and some of the things that I've shown you, I think that these answers are becoming a little more clear. That, yes, there is a need for SGML. It might not be for you. It might be for someone else. But there clearly is a need for it outside of just the HTML application. But HTML in itself is not a good

format to put all of your documents in. That up-translation problem that you run into and what happens downstream, what are you really doing?

I think the answer to these questions really lie in another question to you that you really need to really think about. And that is, what are you doing right now or what do you plan to do with your information in the future? And maybe the possibility of using some of the additional SGML features, you may be able to benefit from this and maybe not to a full-blown SGML application, but just kind of thinking about how HTML and SGML are moving forward together and that we can actually help to guide that.

I think many people are finding themselves caught up in the limitations of HTML. The whole idea, though, is that HTML was designed to be simple, and as it's evolving we might be able to take advantage of some of these other features that we're enabled with. And keep in mind that SGML is always an option for you, putting SGML at the center of your solution and using HTML as one of the published formats that come from that central repository. That might not be for everyone.

What you need to think about is what are you doing with your information. It might be something, not to the extent of SGML, but rather than authoring everything in HTML, maybe you'd look at authoring them in a structured word processing environment and then filtering that information to HTML. So you always have that original source to reuse in different ways rather than taking it down to that bare bottom, lowest common denominator of HTML where you won't get as much reuse and access to that information later. And that's the whole point of this in the first place, is access and reuse of this information.

Just remember, it's not a battle. HTML and SGML are not fighting each other. They really can work well together. There are a lot of powerful features that SGML gives us, and HTML is just sort of tapping very lightly into those. Where they're going to go and how they're going to evolve, I don't think anyone really knows. But as we're looking at how we're going to develop our solutions for our information, these are just all things that we need to be thinking about.

If you would like to find out more specifically about SGML, we do have training courses available through InterLeaf. There's a number on this handout here that you could call if you wanted to get some more information, and we have different types of classes that you could look into if you want to find out a little bit more.

W: [inaudible]

Diane Sandstrum: Yes, you can. There are a couple of different approaches that you could take to do so, whether it's a conversion process that you take that document through to put it into, to take this rich SGML format into HTML. And something that I didn't actually tap into were some different ways and other approaches that could be taken for that. A lot of this is up for discussion.

What is the best way to make this link between SGML and HTML if you want to do both? The link could possibly happen from either side. There could be something that's controlled in, say, the DocBook DTD that would enable you to provide information about, well, this is what this is in SGML. I mean, that's clearly defined; but what would that mean if I were in HTML, or what element would that map to?

Eric Severson: I was going to say that one of the important answers to your question is to say "no." There is, in fact, not a standard way to do that, and that's part of what we're saying in adding some color to the factual stuff of this tutorial. What you have to do is you have to be

thinking of DocBook as, “how do I take DocBook and compress it down to what I can express in HTML?” And far as I know, the DocBook people have not formalized anything like that yet.

There are various ways, as Diane said, that you could implement that, but there is no standard method, not just from a technical implementation standpoint but even from a mapping [standpoint]. There might be disagreement as to what element goes where in HTML, but I’m proposing that if you’re not thinking of it that way you’re going to end up with two different worlds, and you really do need to relate them, even if only conceptually, so that you can make that translation.

W: [inaudible]

Diane Sandstrum: Yes, actually, there are products out there. InterLeaf has a few different approaches that you could take if you have SGML information that you wanted to get into HTML. We have a product that would work directly on the SGML called *SGML Hammer*, and you can basically map these elements through these procedures. You specify for this element, make this output, and you would do this conversion from SGML to HTML.

There is another approach with the InterLeaf products that you can take. There is an InterLeaf SGML offering tool and application tool where you can bring your SGML into the InterLeaf environment. The whole idea behind all the InterLeaf products is to focus on the structure of the components of your document. Once you take this SGML into this InterLeaf world, per se, there are other tools; we have *Cyberleaf Tool* that automates the conversion from any word processing format basically to HTML.

But there’s another route to get to the HTML from your SGML. You can either do the straight conversion or go through a structured word processing environment to do that. And so, yes, I don’t think it’s necessarily widespread, but there are tools that are available and I think the more tools that are out there that help that process the more people will begin to look at this as a viable option for them.

Eric Severson: And, again, a point we’re trying to make is that with *Cyberleaf* or other tools that start from word processors and go to HTML, there are two ways you can look at that. You can look at it as kind of a legacy data conversion tool, and “let’s get this junk out of the word processor and into where we want it,” [into] HTML; or you could look upon it as sort of a production process, a publishing process that says that every time we need to fill the buffer with HTML, so to speak, we use this to go from our actual source information into whatever the latest version of HTML happens to be.

W: [inaudible]

Eric Severson: Well, then you maintain control of your source data, isolating yourself one step from all of the variations that are going on in the HTML world, plus you also are able to control your use of HTML in a standardized process so that you don’t have a hundred different people doing a hundred different things with HTML. As you get into things like formatting attributes and things that really bind a particular format or viewpoint into the HTML, you’re going to basically end up with an out-of-control situation.

M: [inaudible]

Diane Sandstrum: It could be done, actually, with a combination of products. I would think some type of our DM, which is our Document Management piece, used with something like the *SGML Hammer* to automate the conversion of that as it's being put into that repository.

Eric Severson: An InterLeaf specialty, I should say, is to set up these kinds of production processes at whatever scale — production sounds like a pretty high-level scale — but I mean that in the sense of, “I do it and it could be I do this in *Word*, or a simple use of the InterLeaf authoring product, and then I punch a button and bang, bang, bang, I go out and I serve up a chunk.”

What's missing, I think, in the InterLeaf product line right now is really the Web server connection. That's something we've identified as an enhancement, and you can look out there and see who's here, but I believe there are some other early entrants into that, solving that kind of problem.

M: [inaudible]

Diane Sandstrum: The product, the *SGML Hammer* product, would be best served with that and it might be in combination with something or some kind of document management layer. But the *SGML Hammer* is a batch processing tool that could handle that.

M: I have a technical question about the standard. In the SGML standard, is there anything that stops you from declaring parts of your DTD in a document?

Eric Severson: I think the answer is no, there is nothing that prevents that. But that's part of the reason for that. What you do in the document instance is that you always refer to the DTD as an entity. Let me see if this is the answer to your question; I know what people have done is to refer to a main DTD with those parameter entities, and then underneath that redefine those parameter entities, and it takes the last definition. So, effectively, you're overriding in your document instance what the main template DTD had in it.

M: Is there a reason why you couldn't put [inaudible]?

Eric Severson: Yeah, that's a very interesting question. There's nothing in SGML that would prevent you from doing that. I'd actually have to think it through a few more steps to be sure of what the implications would be in my own mind, but I think the question would be, “would that provide a standardized enough mechanism that browsers could easily take advantage of that?” The answer is probably yes, it would, and it's really just a matter of the most practical way of setting it up so that browser vendors are likely to say, “Sure, that's easy enough. Why don't we just take advantage of that?” as opposed to saying, “Oh my gosh, how arcane. We're staying out of that.”

M: [inaudible]

Eric Severson: Yeah. By the way, it's an interesting example, the *Panorama Pro* product. I guess we didn't completely describe that. For those of you who are not familiar with it, *Panorama Pro* is essentially an SGML browser. It can be fired up under *Mosaic* or *Netscape* to deal with documents that are typed as SGML. The interesting thing about *Panorama Pro* is that it has a separate file that has to be defined by the user that essentially does this kind of mapping that I'm

talking about here. It's yet another example of how you might implement it. It's a map that says, "See this element called Abstract in the DTD? That is going to get mapped to 'P'."

About a year ago I actually rustled down a person at one of the WebWorld shows who was demonstrating *Panorama Pro*, and I said, "You've got to show me. Get out a Windows, let me see in DOS. Let's go down and look at what's underneath this, because I do not understand how you can simply read any SGML file as it's served up over the Net. There has to be something that provides this backbone." And in fact they were able to show me that same mapping.

M: [inaudible]

Eric Severson: The SGML world is working on a standard way of representing formatting or semantic kinds of information that can be attached to these generic objects. There is a companion standard SGML called DSSSL, "Document Style and Semantic Specification Language." I once did a presentation where I had Jerry Seinfeld in spirit adding a comment like, "What's the deal with the three S's? How come we can't get along with two S's like every other word in the English language? I mean, can't these people show any self-control?" But DSSSL, kidding aside, is formally the mechanism by which you do that.

The problem with DSSSL on a practical basis has been that it's so exhaustive and comprehensive that nobody has found a practical implementation. One of the things that *SGML Open* is working on between the vendors is actually to come up with some kind of subsetting of that which can make a practical solution. But *Panorama* right now has its own propriety. I mean, it's expressed in SGML, but it's its own application for styles.

Other questions? Anything that you were hoping you'd get out of this tutorial that you didn't? Well, I guess I'll take that as a good sign.

Diane Sandstrum: Either that or there's not enough time.

Eric Severson: Or you got nothing out of it. Yes?

M: [inaudible]

Eric Severson: I have in my briefcase, I believe, a reference on the Net to some of this. It'll take me a moment to dig it out, but I'm happy to do that if you want to stick around. That just came over in the last few days.

Well, thank you very much.

TUTORIALS INTERNET TOOLKIT FOR THE MACINTOSH

SPEAKERS

Kevin Savetz

Computer Journalist

Braddlee, Ph.D.

Network Information Consultant, NevadaNet

[Due to an equipment failure, the first ten minutes of this session were lost.]

Braddlee: I'm supposed to stand really close to you, so we'll just...

Kevin Savetz: Configuration stuff...

Braddlee: This isn't a very... because this job is not very sexy, it'll do redactive or delete different characters for erasing...

Kevin Savetz: So, so for example, if you're trying to edit something and you're in Control-H, Control-H, Control-H, that may be one thing that you would want to change — switch it from backspace to delete.

You can do, you know change the colors, and by-the-book information changes... and all of that good stuff. We try to... In Halifax, it's kind of standard you Control-F to pause output and you Control-Q to resume output. But if your using E-max or some other UNIX Editor that wants Control F to save, then it's a bad thing, because you could Control F to save and all of it's across the screen output. So, you can change those commands as you need to so that you can use the full functionality of your editor.

Braddlee: I think that pretty much shreds it for Telnet.

Kevin Savetz: If you're interested in Telnet or any of these applications, I don't know if Brad has said this — they are listed in your handout — pretty much everything we've talked about and more is in the handout. In addition, there will be an on-line version of this handout which we hope to keep updated on a more-or-less regular basis, and it will help directly link to all of these tools. So if you just put this one page's URL in your hot list, you will be able to very quickly bring up the most recent editions of any tool. And I will give you the URL [inaudible] that's on the screen.

Braddlee: Actually, it's on the list, on the handout.

M: [inaudible]

Kevin Savetz: Yes. And basically it will be an updated list of the handout that you have. Next up on our list of tools to talk about is FTP, which is the Internet File Transfer Protocol. Very briefly, FTP allows you to move information from a machine on the Internet to another machine; present programs or data, weather maps... pretty much anything. A very common use of FTP is something called anonymous FTP, which lets you go into a public server and get information, usually programs, that are available to the public. Not all FTP sites are open to the world — they're not all anonymous FTP sites, but those that are tend to be very popular. You go in there if you want the latest version of a freeware or shareware application. You can go in

there and download anything you need, including most of these tools that we're going to be talking about today. There are several different programs available for anonymous FTP, or FTP anonymous or non-anonymous. There two biggies are *Anarchie* by Peter Lewis, shareware and *Fetch* by the University of...

Braddlee: Actually Dartmouth, Dartmouth College.

Kevin Savetz: Dartmouth College. It has been... we'll look at both of those. It has been the case that *Fetch* hadn't been updated for a very long time.

Braddlee: Almost a year.

Kevin Savetz: Almost a year...

Braddlee: Which is a very long time for a lot of these guys.

Kevin Savetz: ... yeah, that's ten years in Internet...

Braddlee: Right.

Kevin Savetz: ... so, *Anarchie* really... it was still being updated and it... even if you like to interface with *Fetch* better, you kind of had to use *Anarchie* because it was the only one being actively maintained. About two days before the show started, I discovered that somebody's updating *Fetch* again. So it's in through 3.0 BETA — *Fetch* is out. So now I think there are about two viable FTP clients, and that's a good thing, so pick one. We'll also do a quick look at *SnapSure*, which is a commercial FTP client — which is fine. Frankly I like *Anarchie* better, but to each his own. We'll look at all three of those. Should we start with *Fetch* ?

Braddlee: Take a look at *Fetch*.

Kevin Savetz: Do you want to look at the old one or the new one?

Braddlee: Let's look at the new one, because I think... it seems to be stable enough. Some of the things that we are going to show you are Beta. Part of the reason we're doing that is because we want you to see what's current. If there is something that's Beta, chances are there will be another non-Beta release version of that application. We'll tried to let you know that on the handout, and give you pointers to both. That will also be true on the Web site... that you'll have directions to both and you can get either one. But, if we're showing you the Beta (maybe you want to move away from the fan, if you can't hear, come on over here and you'll be able to hear okay. I think they're still, they are still trying to work) anyway, so if there is Beta that is stable, we will show you the Beta...

Kevin Savetz: And, occasionally, if it's not stable, but if it's really interesting, we'll tell you about it.

Braddlee: That's right.

Kevin Savetz: *Fetch* — this is the opening screen for when you run *Fetch*. So you can open up a connection, and in the newest version, there are shortcuts so you can save bookmarks to your

favorite FTP sites that you go through commonly. I'm going to open up a connection to an anonymous FTP site... gave it the host here — just write anonymous and it asked for my e-mail address, and I put okay.

What you are about to see is... this is the main *Fetch* interface. It's about to bring up a list of files available, actually it's folders, at this FTP site. And this is pretty [inaudible]. You flip the folders, and if you want to go to a directory, different directories, such as this public directory, you double-click on it and a little dog runs and it's all very cute and nice. Then you can go into the mirror of the InfoMac archives, for the files of the Macintosh.

Braddlee: You may want to explain, just real briefly, what the InfoMac archives are. Okay. Basically InfoMac... there is a collection, a distributed collection of Macintosh resources — not just for Internet stuff, but pretty much in any area that you would be interested — and called InfoMac.

There is the home InfoMac archives which is AMISH...

Kevin Savetz: Stanford.

Braddlee: Stanford, okay. But there are mirrors of that archive across the network. The one that Kevin is at, at the moment, is America Online. So really what you can do is — one of the things you'll see in *Anarchie* is there's a list of different bookmarks for the different InfoMac mirrors and always feel free to shop around for the one that will actually let you in, because they all tend to be busy. But they are a great resource and a great set of tools.

Kevin Savetz: Mirrors are a great way to get into a site which is overloaded because it is very popular. I happen to like the one in America Online: mirrors.aol.com. Because it's relatively new and they've got a big server, and they're... it's usually pretty easy to get in, especially versus the real InfoMac archive, which is very, very popular. I've navigated here to the virus directory. This is not viruses, but a virus protection tool.

Braddlee: Gosh.

Kevin Savetz: Yeah, and if you, for instance, want this *Infection*, which is a great three-word virus program, you can click on it and get the file. We'll go through the motions of actually downloading it to your computer. Oh, this is cute.

Braddlee: Yeah.

Kevin Savetz: This is the first time I've used this version of the program, so I'm just as surprised as you are. We save it to the hard disk and the cute little bar graph is going to tell us how far we are into getting the software.

Braddlee: And it will tell you things like just how slow your PPP connection is, and...

M: [inaudible]

Kevin Savetz: The question is, "Why does your bits-per-second change in the estimate. And, I think it's pretty much true in any program. In my experience, the more information it gets, the better it can make a judgment on the average of how fast it's going. It's not that your speed is fluctuating,

it's that it actually has more time and more information to base its guesstimate on. It's trying to make an average. You agree?

Braddlee: Yeah.

Kevin Savetz: I just made that up, so...

Braddlee: No, that's accurate. Yeah. Or we're both wrong.

Kevin Savetz: So anyway, we're getting into the program, and as with any FTP... pretty much any single FTP for Macintosh, you'll find that it is compressed and stuffed in an archive and you need to uncompress it. And there is a great freeware program called *Stuffit Expander* — which if you don't have it, you need it. You get your things that you downloaded, you drag and drop it onto *Stuffit Expander* and it miraculously uncompresses it, whatever it needs to do and then you can actually use the uncompressed workable product... there's a question?

M: [inaudible]

Kevin Savetz: Is there a danger of viruses in the FTP? I highly recommend using *Disinfectant*, or whatever other program you want, to virus check any program you download before running it. You can get a virus from any program that you run. Well, this is going to change, but in general, downloading a text file [inaudible], GIFF file... programs can. Recently some brilliant person came out with a virus that works in Microsoft Word 6, that is basically a virus that works within the macro language, which apparently can be kind of screwy, but if you don't use Word 6, then it's not a problem.

Basically when you download anything, you should virus check it first. In my experience, I have never had a problem. I use the major Macintosh software archives, and generally they do virus checks before putting it on-line. However, don't trust them. You don't know if the guy was in at 3 a.m., and the person doing the archives was hired to virus check it... it's not worth the hassle if your hard disk gets corrupted.

Braddlee: And something I try to do — I've been doing Internet stuff since about 1988 — and in that time I've acquired one virus, and that didn't come off the Internet.

That actually came from our Apple Rep. However, I do use *Disinfectant*. I almost never find anything unusual, and once in awhile it will ring a false alarm. But I run it just because I would rather do that on a regular basis than be stuck, and *Disinfectant* is a very good tool. Another thing that we try to do is go to the source. Go to the source: if you're going to get a copy of NetScape, go to NetScape.

Kevin Savetz: Get it from NetScape, rather than from...

Braddlee: From a hacker or a pirate.

[A brief portion of the tape is blank.]

Kevin Savetz: You used to have to enter every single Internet program that you ever got. With *Internet Config*, you tell it all that information and then, if you have *Internet Config* compatible applications, they will ask *Internet Config* for that information and therefore save you the time and the trouble of entering that stuff into each new program — each new version, ad nauseam.

When they first came out there weren't any *Internet Config* compatible programs and I would say there are about five or maybe ten now...

Braddlee: All the Peter Lewis programs because he wrote *Internet Config*. *Fetch* is. I think [CUC] might even be...

Kevin Savetz: So, it's an open standard, and it's becoming more popular. And, I think, in the long run, it's going to be a way to save us all a couple minutes of going "What was my new server again?" and typing in `news.screws.net.food.bar` or whatever it is.

Braddlee: And it will also — for people who set up machines for other people — allow them to set up the machines and configure them once and then the users will be able to add new applications, and not have to wrestle as much with configuration.

M: When downloading stuff, I noticed that in a browser, sometimes it will do "FTP colon" or, now that it's going to just use FTP to acquire things — is this maybe a trend toward just going on a page and just clicking on a reference? The program comes down to your Mac, it unstuffs itself and then it installs and sets itself up automatically.

Kevin Savetz: Right.

M: Day by day it gets easier.

Kevin Savetz: Yeah, things are getting easier. I think there's a trend, we're slow... I don't know if we're ever going to get all the way there, but I think things are slowly moving to the direction that you're going to have one program, be it Netscape or some other Web browser that can do FTP within one program. So, if you want to — and there's a link so you can click on it — FTP will uncompress it, and then you can install it right then and there.

But, at this point, there are certain functional advantages to using a dedicated FTP program. For instance, Netscape cannot upload FTP programs. Also, Netscape will give you one thing at a time. If you want to download all 20 of these virus programs, you can't do that in Netscape. But under *Fetch* or whatever, I can select a range of information and download them all at once — if you want to horde software and set up your own archive or something like that. So, I think very slowly we are moving towards an innovative package, and I know that in the newest version of Netscape Beta [it] will do e-mail, as well, and has a better use.net news group interface. So one day it will be one 12 megabyte program that will do it all. But for now we're not so lucky. So we have to have these conferences and talk about the differences. Besides variety is the spice of life.

Braddlee: That's correct. There's also two perspectives on this. One of which is sort of the Swiss army knife, Netscape is the only tool you'll ever need kind of perspective; and then the other, which is the you'd kind of like to have a tool kit where you have different tools, even though they may have been designed by different people and work somewhat differently, [each] has its own unique attributes and features that make it more or less endearing than something that's maybe a little bit more homogenous.

Kevin Savetz: This is *Anarchie*. This a shareware program by Peter Lewis. One of my favorite things about *Anarchie* is the About Box. The more you download, the better rating you have. Currently, on this machine, I'm a Power User. It starts you up at newbie and you get to Power

User, and on my Mac at home I'm currently up to Net Destroyer. I'm not sure if that's good or bad, but anyway... *Anarchie* comes with a much more complete bookmark list than any other FTP program that I know of. So even if you don't know where you want to go, or you're just kind of cruising for good stuff, there's just this huge list of yummys out there on the Internet.

To show you interface, I'm going to go to the same site that we just went to before so you can kind of... we'll get *Disinfectant* again. So I'll hit "list". I happen to like this interface here, these boxes can tell you how much more downloading there are and [that] you need to have. We'll click on the viruses directory here and we'll bring up a separate window, which is kind of nice because if you go, "I really didn't want to be there," you still have this other window that you can pop back to. (The T-I all to ourselves, and we're still waiting.)

So here's *Disinfectant*, we'll double-click on it, and it will download the program once again. So the interface here is Mac-like. It's a heck of lot better than using a command-line FTP interface, which is just a horrible experience, and if you've never had to do it then good for you.

Braddlee: I do a lot of construction, introductory UNIX Internet classes for people in Nevada and pretty much I can figure — if we are teaching people how to do UNIX FTP — it takes about an hour to cover the basics like how to get a file down — and particularly if they're doing it in DOS.

Kevin Savetz: In the olden days, like, a year and a half ago, if you were downloading anything, you would have to download it to a UNIX machine and then transfer it to your Macintosh, and that was just a huge pain. So, here we go, we're downloading something straight to the Macintosh. It'll be here in 54 seconds and, it will be safe from viruses of all types. And we're very impressed. Okay. We'll abort, and go on to...

Braddlee: Now, did we actually search for anything?

Kevin Savetz: Oh, you're right, I forgot the...

Braddlee: The fun part.

Kevin Savetz: ... the fun part. *Anarchie* is a combination FTP client we produce on, also a *Archie* client. *Archie* is an Internet tool for finding software on the Internet. If you know that you're looking for *Disinfectant*, or whatever, and you don't know where it is, you can just type in *Disinfectant* and it will give you a list of where they are, and then you can just click on one of the things and it will send it right to you.

Integrating *Archie* and FTP is just a brilliant idea, and I've never seen it done anywhere else, and we... this is still one of the things that Macintosh people can do that Windows users can't do. Not that it can't be done on Windows, but no one's sat down and wrote the program. Do people understand what *Archie* servers are? Okay. *Archie* is a system which systematically checks public FTP sites for the files that are available on them and then indexes them by the name of the file and by its location.

So, by using the *Archie* client on *Anarchie*, will select one of the 10 different *Archie* servers that have these databases of information, which should all be fairly similar. You don't really have to worry about choosing an *Archie* server on the basis of the content. It's pretty much choosing on the basis of traffic, whether or not it will let you in. So that you ask the *Archie* client what the name of the file you want is — for example, *Disinfectant* — and so it's going to take a look

at the *Archie* server at *archie.internet.net*. He has currently selected it as a substring so that it will look for *disinfectant.hqx* or *Disinfectant* whatever else.

Braddlee: We'll try to do it using two different servers at once. Neither one is talking to us.

Kevin Savetz: Right, neither one is talking to you. In looking at *Archie*, if you see down at the bottom of this, the barber pole or just above the little barber pole, there is a finish guesstimate. It always says 15 minutes to start. If it stays at 15 minutes for more than a minute or two, you're basically not getting anywhere. One of the ways you can tell that you've actually made a connection is when you've got a packet received. If you don't start seeing two packets received within a minute or so of the time that you connect, then it's probably good to try another site. The ones that I have fairly good luck with are the Taiwan, the TW and the Italy.

Braddlee: Here's the Italy. In my experience, I love this program. And as I understand, it's not a failing of this program, but *Archie* servers are generally very loaded, so it's hard to get into them. And, also apparently there's some low level protocol problem with *Archie* servers where they don't always wake up when *Anarchie* tries to go in there and get the information.

Kevin Savetz: Oh, really.

Braddlee: Peter Lewis explained it to me once, it went right over my head.

Kevin Savetz: Okay, so it's the *Archie* client [that] knocks on the door of the server and...

Braddlee: And, the server...

Kevin Savetz: ... says nobody home.

Braddlee: Right, even if it is up. So sometimes you try to use *Anarchie* to do *Archie* and it just doesn't work — that's life on the Internet sometimes.

Kevin Savetz: Hey.

Braddlee: Hey, we're getting one. So we're talking all the way to Italy. And, Italy will talk to us. Is there a question back there?

M: [inaudible]

Kevin Savetz: Okay. They're built right into the *Anarchie* client. So, what you can do is... From *Archie* it has a list of all the living and breathing *Archie* sites.

M: What about *Archie*'s comic book friends.

Kevin Savetz: Well, *Veronica*. I'll talk about *Veronica*. *Veronica* actually is something that was developed by a friend of mine, Steven Foster, [at the] University of Nevada. *Veronica* is a tool for searching across *Gopher* sites, in a similar way to the way that *Archie* searches across FTP sites. You'll see programs similar to this when we look at the WorldWide Web — for example InfoSeek and Lycos and these kinds of tools for searching for WorldWide Web information.

Veronica is a companion to that. *Veronica* has... *Veronica* and *Archie* suffer from some similar problems in the sense that they are over-used and underfunded.

As far as I am aware of, all of the *Archie* servers that are out there are run as free services. Nobody's getting paid for doing them, very much in the same way that *Veronica* — we don't have any underwriting — no commercial funding is supporting *Veronica*. This means that unlike InfoSeek and some of these other tools that are getting commercial money behind them — they don't get a strong support.

Something I think probably we should have talked about in the beginning is, if at any point — our goals is not necessarily to cover a whole bunch of applications, but for you to have an understanding of those applications as we go through them — if you feel we are talking over your head, there are not stupid questions. This is an introductory session. If there is something that we are assuming [as far as] knowledge that you don't have, please feel free to stick up your hand and interrupt us and ask for an explanation.

M: Well, when you logged in with *Anarchie*, what did you type in for path? Did you hit the dialogue...

Kevin Savetz: I've done two things. When I did the initial FTP, when I brought up this menu here, I put in the machine name — the one used was mirrors.aol.com, because that was the one that I wanted to go to.

M: How did know that was there?

Kevin Savetz: Because I've been there before, honestly. But this might have been an FTP site that a friend gave me or that I got in Internet Life Magazine or it's... and if you don't know the FTP site, then you start with the *Archie*. You start searching with *Archie*.

Braddlee: Right.

Kevin Savetz: So, if you don't know where to go, you search. But, if you do, you can go straight there. And specifically to your question: if you don't know the path, it puts you in the root directory — it puts you in the starting place. I happen to know that I wanted to go to a certain place, so I put in pub.info.mac because I knew that's what the directory was called. In the user name field, if you have an account on the computer, you can put in your user name and your password, and if you don't you can leave these blank, and it will anonymous FTP you into the site.

And then the second thing I did was when I did the *Archie* search, I just told it what server I wanted and what I wanted to search for. And, we had a bit of a problem waiting for it, but when it finally came up, it presented this list of pretty much every file that *Archie* knows about that's available by FTP which has the word "disinfectant" in the name.

And, basically, this looks like a FTP list, but if you look over in this column you can see that you've got France and Sweden and Italy and the United States. There's copies of *Disinfectant* scattered everywhere. And, if you look, you can see that we've got *Disinfectant* version 3.4 and version 3.5 and some other files that aren't *Disinfectant*, but have the word "disinfectant" in the file name. So, we decided on the University of Michigan, which is relatively close — as opposed to getting it from France. And then we can download it. It will try to go out there and get the program for us.

Braddlee: And the links in here are only going to be as good as the information on the *Archie* server. So if, for example, since the last time *Archie* went out and talked to a particular FTP site, the system administrator has moved a file, then you'll get a broken connection. It will just say, "Sorry we could not find that file."

Kevin Savetz: See, how well I demonstrated that for you?

Braddlee: Thank you, no such file or directory, yes, exactly.

Kevin Savetz: And, then you can just try to get it from somewhere else. Or, if the server is just too loaded it says come back later, you can just hit the retry button and it will try to get the file again.

Braddlee: Do you want to show people what FTP looks like coming from a Mac? Or do we want to do that later?

Kevin Savetz: Let's do it later, I think. So, in brief, that is *Anarchie*. And, I don't want to spend a whole lot of time on it, [but] take a look at *SnapSure*, which is a commercial product — which is another FTP client. The best thing about *SnapSure* is that it's interface is almost completely Mac-like — it's almost like still being in the finder. I'm going to hide others here to show you what it's like.

We're going to open a connection: mirrors.aol.com. Now, it's going to bring up a window that... it's easy to forget that you're at an FTP site and you just think that you're in the finder doing your normal Macintosh thing, but after it gets it's information... we'll wait patiently... it will present some folders which look just like the finder. And if you want to navigate the finder, you just double-click on it, and when you want to get a piece of software, you just drag it to your hard disk — just drag it right over, and it will just copy it over!

Braddlee: Now, this is shareware, correct?

Kevin Savetz: This is a commercial application. It is by Software Ventures. I think it's about \$50.

Braddlee: Making it probably the most expensive server software that you will see today.

Kevin Savetz: Yeah, the most expensive server software that you will see today.

M: Does it support "puts" as well as "gets".

Kevin Savetz: Yes, it does. If you want to put something — a folder or a single file — you can just drag it right onto your snatcher window and it will put it in that directory. So, that's kind of nice. And apparently, *Snatcher* does not want to be demonstrated today. It's just whining about something. It got in, but anyway. I wasn't going to spend much time on that anyway.

Braddlee: Okay.

Kevin Savetz: So, in brief, those are the three major FTP clients. A little bit later, we'll talk about servers including an FTP server for the Macintosh. Any questions at this point? Anything at all, anyone? Anyone? Okay. I suppose next up is e-mail?

Braddlee: Yeah.

Kevin Savetz: When we did this six months ago, I announced that the only e-mail that you would ever need for the Macintosh — that was viable, that anyone would want to use — was *Eudora*. *Eudora* is still a great program, but now there are two other decent programs that are worth mentioning. So, we'll talk about all three of them. *Eudora* is still my personal favorite, but the other ones do have some, some great benefits that *Eudora* doesn't have. *Eudora* is a program from a company called Qualcomm, and *Eudora* comes in two versions. There's a freeware version which is very functional and pretty darn useful, and there is also a commercial version called *Eudora Pro*, that comes with... I don't know what it costs, \$100 or so?

Braddlee: \$69. I think it's well under a hundred.

Kevin Savetz: Less than a \$100, probably about \$69, and it comes with Internet access. If you don't have any, you'll be able to send e-mail via their mail server. It also has some extra features: some filtering features and some other sorts of tools. I am going to be showing you *Eudora Pro*, I think that's what this version is. So you can get an idea of what it looks like. I'll bring up my... hide others here and clean things up. They have an in-box. [I want to] show you a mail box with some mail in it — there we go. There's all our mail. Oh, I've got mail from my mom — incredible! My mom is on the Internet. So you've got your, the in-box, which is where the incoming mail is.

You can see all of these little ones with the — they're new — I haven't read them yet, and then there's the ones without the dots that I have read. There's the out-box, which is stuff that is queued to go out, but hasn't gone out yet. You can find out who sent you the message, when it was sent, the size of the message... it's, 20K, 2K, and then the subject. Also *Eudora* has the ability to let you prioritize mail, so if you're sending something that you feel is very important, you can change the priority and make it high priority or low priority.

Braddlee: Is that the little chain letter you just got?

Kevin Savetz: The chain letter I just got, it would be a very high priority message, I'm sure of how I can make money fast on the Internet. And, in order to, for instance, read a message, simply double-click on it. Here's something from some random person on the Internet. There's actually no body in this message, but that's okay. So, you know who it's from, and the subject, and date, and if you want the gory details of all the headers, you can hit the blah, blah, blah button and it'll show you all the headers that you don't normally care about. So it's nice that it kind of hides that from you. You can, of course, delete messages, forward them, reply to them. It'll let you reply to the person who sent the message or reply to everybody who received the message — a group reply. You can also redirect the message, which is kind of a unique feature which is hard to explain. It basically lets you forward a message without putting the little forward brackets that you normally see. It makes it look like the message came from somebody else. It says redirected by you, but it's basically — if somebody sent you a message that you feel should go to your associate, you can just redirect it and hand it to somebody else and get it out of your life.

To send a message — mail message, new message — it's pretty straightforward. Type in the address, the subject and a message body. *Eudora* supports signatures. Actually *Eudora Pro* supports two different signatures, so I have my normal one that says who I am, and if you want a second signature, you can change the John Hancock to use your alternative signature if you like. *Eudora* will also encode programs in various ways. If you're sending an attachment to

another Macintosh user, you might use *Bihex*, but you can also use UUencoding, if you're sending something to one of those lowly PC-using vermin that you may be associated with.

Braddlee: Or UNIX system admin...

Kevin Savetz: Or UNIX System Administrator, or whatever that is. Also, I don't know why they don't call it MIME, but Apple Double is MIME, and so you can do MIME attachments. Apple Single is something apparently that is obsolete and no one ever uses, but it supports it.

Braddlee: Do you want to explain what MIME is?

Kevin Savetz: Explain what MIME is.

Braddlee: Okay. MIME is an evolving set of standards which eventually are intended to deal with multi-media Internet e-mail: so that you will be able to attach video, audio, text with fonts — what a radical concept — to your electronic mail and have it integrate seamlessly. Right now, it's fairly crude.

Basically what it does in the context of electronic mail is it allows you to attach a file in such a way that another Internet mail program — such as Pine or Elm or any of these other things that we are going to be looking at — knows in a standard way how to interpret it. One of the things that MIME does is that the Internet standards for mail don't deal with binary files — they don't deal with actual software. Anything that has Control characters, any of that sort of more elaborate stuff in it as characters in its contents.

Kevin Savetz: And God forbid, you should want to use fonts or colors or fonts of different sizes in your e-mail.

Braddlee: Right.

Kevin Savetz: I mean, absolutely unheard of, but MIME is going to let us do that.

Braddlee: Eventually, some day.

Kevin Savetz: And it's still an evolving standard, and it still doesn't work, but real soon now, you'll be able to do that.

Braddlee: And I think one of the things that's interesting too is that MIME is starting to show up in WorldWide Web stuff in a fairly frequent manner. So it's not going to be just for your e-mail, even as though it's actually a standard that was developed and intended for electronic mail. But, for the time being, if you take that copy of *Disinfectant* that we've been talking about for the last hour, if you have a copy of that that you really need to send to your friend that doesn't have the slightest idea of about how to FTP, you can attach it to *Eudora* mail — it will translate it from the binary form into ASCII text form — and your friend can bring it back down using *Eudora* and it will unhook it from the mail automatically.

Kevin Savetz: So, I've created a message, I put an attachment, I've decided I want to *Bihex* it, and I can queue the message — this is nice little feature: that if your sitting on a bus or in the airport and you want to reply to your e-mail, and you don't have an connection, just queue your messages and it'll put it in your out-box with a little Q by it and it's cute. And the next

time you log in, you can send your mail and check your mail and it will send your queued messages. (Oh, four messages...)

Braddlee: Hey, in the last hour, yes.

Kevin Savetz: ... like in the last hour. So it'll check my mail and it'll check my message, which I just sent to a test machine that's going to bounce it back to me and say, "Hey, I got it," so that we can prove that it works.

Braddlee: The little things that are flying underneath the message that's remaining to transfer, that is the *Eudora* client talking to Kevin's mail host.

Kevin Savetz: You'll hear a little beep — it said I had mail, although the sound isn't very loud.

Braddlee: *Eudora* uses what is known as the POP Protocol, Post Office Protocol, for exchanging mail. It's one of a couple of options. The nice thing about POP is that it's real solid and it works. The bad thing about POP is that it's kind of brain dead and simple, and it doesn't allow you a whole lot of flexibility about where you keep your mail or how you store things.

Kevin Savetz: Right. If you keep your mail on your laptop and on your UNIX machine, but sometimes you read out at your home computer, POP isn't good at that. There's another protocol which is better at that called "I-Map," but I'm not aware of any... there's that one tool...

Braddlee: Why don't we just... I think we actually have a copy of it here, but if you're in an environment where, for example, back home in Nevada, I work statewide — I commute between Reno and Las Vegas. I also go out to a lot of the other spots in the state. *Eudora* for me is not a good tool, because I have two options, I can keep my mail in my in-box or I can have it downloaded to the computer that I'm working on — which means that I either have to carry my laptop with me everywhere I go, or my mail gets fragmented, which for me is not very satisfactory. There's another protocol other than POP called "I-Map," which is a little more sophisticated, and *Mail Drop*, which is listed on the second page of your handout is a brand new version of a mail client from Bailey University that does work with I-Map. Now, it requires that your Internet provider have I-Map support running on their mail host.

Kevin Savetz: As it is with using POP with *Eudora*, they need to have POP as well...

Braddlee: Right...

Kevin Savetz: Pretty much any good Internet provider will have these things.

Braddlee: Should have both, right. And *Mail Drop* gives you some more flexibility. It means, that, for example, for me I use UNIX mail... a program called *Pine* fairly frequently... and I store up my mail in a lot of files in folders on my UNIX account. *Mail Drop* allows me to retrieve mail from those folders, it allows me to keep or delete mail from my in-box, it allows me to file things and have all that work happen on the remote host, so I don't have to bring all of my mail down and have it on the PowerBook. If you're doing mail in one place, the only place you read your mail is in your office, POP is wonderful.

Kevin Savetz: And, therefore, *Eudora* is wonderful.

Braddlee: Well, *Eudora* is a nice program. Anyway it is a really well-designed program. If you're in a case where your reading mail at home, you're reading mail at work, you want to be able to save things in different folders, you want to have access to all of your mail, I-Map and some of you may want to take a look at *Mail Drop*. It's a new program. It looks to me from looking at some of the documentation and things they've written about it, that they are kind of at a transition point between trying to decide if they want to go with a commercial partner — somewhat the way *Eudora* was. *Eudora* was originally a shareware program and it became big business. But, it's worth looking at if that's the kind of thing that you need. And it's basically simple and pretty easy to use.

M: [inaudible]

Braddlee: The UNIX program that I use to read e-mail is called *Pine*, it stands for, “Pine is not Elm,” — *Elm* is another UNIX e-mail practice. This is UNIX's idea of a joke. And *Pine* comes from the University of Washington. It's free software. If you've had to use anything like Berkeley mail, you would give at least a hand and maybe a whole arm to switch to *Pine*.

Kevin Savetz: I'll bring it up. We're now talking about UNIX mail tools. Which, is a completely different tangent, but what the heck. But, if you have to deal with UNIX, and you have to do mail in a UNIX, *Pine* is pretty much your only choice.

Braddlee: However, I absolutely love *Elm*.

Kevin Savetz: Oh, good, we can have an argument.

Braddlee: When I'm stuck using UNIX mail, I like *Elm* a lot better. Not only because it was written by a friend of mine but it works well — they're both easy to use. Honestly, *Pine* is a little bit easier to use which is why I use *Elm*, because I prefer power to ease of use.

M: And Berkeley mail is what?

Braddlee: Berkeley is when you just type mail and you get this horrible little interface and it's all command line and it's horrible. So anyway, but we're not talking about UNIX and we don't want to frighten you away.

Kevin Savetz: That's correct.

Braddlee: Yes?

M: [Inaudible]

Kevin Savetz: It has to have an I-Map demon running. In the same way, if you're going to use *Eudora*, the remote mail host has to have a POP demon running which... and the demon for those of you who are not aware, it's basically just a small program that runs in the background of the remote computer and knows how to handle certain things.

Braddlee: Basically, your e-mail has to come from somewhere and there's a protocol that the computers agree to get your mail to you, and it's either POP or I-Map.

M: [Inaudible]

Braddlee: Yes. The I-Map and the POP are both free by the people who make *Pine*, as well as some other versions but they're out there. And you can... basically if you're a UNIX system administrator you should know where to find them, and if you're not...

Kevin Savetz: You don't have to worry about it.

Braddlee: Even if you don't know where to find them, start at the University of Washington.

Kevin Savetz: Going back to *Eudora*, remember *Eudora*? It has some other nice features including multiple mailboxes. I could stop this message and I can drop it into a mailbox called junk mail stuff I want to get to later, and then I can open my junkmail mailbox and there's a whole list of other things in here. An extra nice feature is filtering. You can set up a filter that will take mail from certain mailing lists.

Maybe you subscribe to some high volume mailing lists. It will get that information. It will look at the two line and say hey, well if this came from a certain mailing list, I don't want it in my mail in-box, shunt it to a special mailbox for your junk mail for whatever so that you can get to it later as a less high priority. Or you might have mail from your Mom your change to the priority is lower or higher depending on what your opinion is. So... and also you can change, just change the... visually change the color of a message on the screen from a certain person so it will stand out so you can ignore it or whatever.

Also Elm has nicknames also known as aliases, so if you want to send... I can never remember Braddlee's e-mail address, so I can just type in Braddlee and it will send it to him automatically. So, in brief, that is *Eudora*. A couple questions. Yes?

M: Yes. With nicknames, can you list several names?

Kevin Savetz: Yes.

M: For an address I mean, more than one name for a mailing list?

Kevin Savetz: Yes. You can set up, in *Eudora*, also in Claris e-mail, a simple mailing list. I wouldn't put hundreds of people on it, but if you want to send something to your work group in there's twenty or fifty people on it, you can just type my buddies or my work group or whatever, and send to all those people at once. If you wanted to send to a lot of people, you're better off setting up a real mailing list. Or if people want to be subscribing and unsubscribing themselves, kind of a public mailing list, I wouldn't use any simple mail program for that.

M: [Inaudible]

Kevin Savetz: Right. The shareware version of *Eudora* doesn't handle UUencode.

M: Does *Eudora Pro* does it translate this down?

Kevin Savetz: Yes.

M: Okay.

Kevin Savetz: Yeah. This question over here came up next.

M: Yes. Does this *Eudora*... does this work well for say setting up a home server at an office where there is several people that would be connected to it as far as getting e-mail and distributing?

Kevin Savetz: *Eudora* and *Eudora Pro* are good solutions for any... just sending e-mail between any group. If you just want to send to five people or any set number of people, it's a very nice way to easily reach...

M: Are people — say they access our front page by the Internet — if they had an e-mail on their first page, first they work in the opposites [inaudible].

Kevin Savetz: Oh okay. Well that's a little... basically, I think what you're talking about, is you're talking about having the Web server do the mailing?

M: Yeah.

Kevin Savetz: And then the mail would go to those people?

M: Right. Yeah.

Kevin Savetz: And so it's going to Bob at whoever.com.

M: Yeah.

Kevin Savetz: You're not going to mail to a URL — meaning that it's basically inside the Web, inside the context of the Web page, [but] there will be a link there saying... bring up a generic mail page so the person can... puts that person's e-mail address in and the Web server handles the mailing. Yeah, this would be a perfectly reasonable...

Braddlee: I'm sorry, I don't know that... how [about] if you had an alias, a nickname in *Eudora* — there's no way the Web server would know about that.

Kevin Savetz: No, no. What you would have to do is you would have to set up a mail... I'm sorry, I thought you were talking about individuals like Bob, Mary, Nancy. If you have a group of individuals, you have to set up a mail alias at a higher level.

M: You don't have to have a specific e-mail name then?

Braddlee: Right. See the way I would do it if I was running a Web server on a UNIX machine, and I wanted all comments from the world to go to Bob, Mary and Joe, I would set up an alias on the UNIX system called Web Masters or something and anyone that sent to Web Masters as whatever.doc would go to Bob, Mary and Joe. That's a function really outside of *Eudora* that's done at a different level.

Kevin Savetz: Which is easy to do in UNIX but...

Braddlee: Easy in UNIX, not so easy in the Mac. A question over here came up first.

M: [Inaudible].

Braddlee: Long messages in *Eudora* splinter into several 32K messages — I hate that. Yes.

M: There's no way to stop that?

Braddlee: No. Basically, if you get a 100K message it will break it down into one of four, two of four, three of four, four of four. Honestly, as I understand it, from sloppy programming and laziness on the part of the programmer because other programs... if you ever use the text editor *BEdit*, it will handle huge messages. But basically it means the programmer has to go out his way and they haven't done that and I wish they would.

M: [Inaudible]

Braddlee: Yeah. This is all actually on my hard drive. And if I move things around, it doesn't affect anywhere else in the world, just in my hard drive. Any more questions at this point? Yes sir?

M: Is there a *Pegasus* mail for the Mac?

Braddlee: Is there a *Pegasus* mail for the Mac? I believe there is.

Kevin Savetz: That sounds to me... is it a commercial program?

M: [Inaudible]

Kevin Savetz: That's not one I'm familiar with.

Braddlee: I've heard of it. There may be and honestly I don't know. Sorry. We'll do an *Anarchie* search at the break. Yes sir?

M: [Inaudible]

Braddlee: For an attachment, you can tell it a default encoding and I have it, I think it's been...

M: [Inaudible]

Braddlee: Some extra scale? I'll bring it up again and we'll see. There's all sorts of little icons up there that will do different things. I wasn't going to get into all of them but I'll certainly answer the question. This is if you want a return receipt, this is if you want to keep a copy of the message you're sending on your hard disk. This one is if you want it to automatically wrap words. And I don't remember what this one is off the top of my head.

M: And all the way to the left?

Braddlee: And all the way to the left: this is the priority. If you want to be high priority it gives you the things. And normal is just blank there. And here is where you change it from *Binhex* or whatever and you can change the default on that. Okay? The next program, which didn't exist until a couple of months ago is called *Claris E-mailer* which is a pretty nice e-mail program.

It's main benefit is that it can check e-mail on other systems other than the Internet. If you have it, it will check Internet e-mail, it will check CompuServe e-mail, it will check *eWorld* e-mail, and it will also check America Online e-mail. It doesn't check Delphi, Genie or any other services. Maybe they'll add that in the future. So basically, if you have accounts in more than one system, you can ask it to go in, grab your e-mail, and it all comes to one place. And, conversely, if you want to send e-mail, you can tell it, "I want you to send this via America Online or via CompuServe or via the Internet," and it will figure out how to route that information there.

I have a bunch of e-mail accounts and it's a pain checking every service everyday. And now I don't have to log... like run America Online to log in and then *eWorld* to log in. You just run *Claris E-mailer*, you pick the accounts, if you have multiple accounts on one system, you can pick the ones that you want logged in and it connects to all of them.

If, in the case of CompuServe, America Online and *eWorld*, you can connect to them via the Internet because they are actually connected by a TCP/IP which is how I'm about to connect this up and get all this mail I haven't checked in days because I've been working so hard at the show.

But if you don't have an Internet connection you can still use this program, and it will actually dial into the local America Online number, get your e-mail, log out, dial into the local CompuServe number and log out. So whether you have Internet or not, this is a nice way to check your e-mail.

You can see I have different priorities here. I have it set up so different accounts — it changes the color of the message so I can see at a glance how important the message is to me. Some of my mail I care about more than other mail.

So it logged into two accounts in America Online and got information. Now it's logging into my *eWorld* account and getting information and now it's going to log into — I don't think I asked it to, but basically it could also log into CompuServe.

Also, there's a service called *Radio Mail* which I'm not very familiar with but *Claris E-Mail* will also work with the *Radio Mail* as well.

M: Is it pager-based?

Braddlee: It's some sort of pager-based system that lets you check e-mail even if you don't have a modem. It will... works over radio instead of over the phone lines. It's a commercial service that costs big bucks I'm sure, and I don't honestly know much about it.

On *Claris E-mailer*... kind of a different feeling to it. You may like it more, you may like it less than *Eudora*. You've got your in-box, you've got your out-box, you've got your filing cabinet which is basically like having my alternate mailboxes in *Eudora*. And it has an address book as well.

A nice feature... the first time I ran *Claris E-mailer*, I wanted to set up my address book and it can import address books from other programs, so I just showed it my *eWorld* address book and my [inaudible] address book and my *Eudora* address book and it just sucked it all in — figured out what it all meant, and now I've got this very complete address book in this program as well. So the configuration time was kept low which I appreciated.

To send a message — I'll show you the interface for that. The same basic information as *Eudora* although it looks a little bit different. We'll send a test message. (I lost my crutch there for a minute.)

We can send a message to... give me an e-mail account. So we're going to send it to my AOL account, and the address is Savetz and the destination is a whole big list of destinations that it can figure out how to send to. We're going to send it to Savetz at America Online. So that's where it's going. You can also choose which service you want to use to send it. So I can send it via my Internet account or via my America Online account.

If you're shy about logging into AOL because you're over your ten free hours or whatever it is, and you don't want to log in any more, then you send it via the Internet and it will get there.

So I can take the same message and I can — I'm adding a recipient — and I can also send it to this other fellow on eWorld. And I can send that via AOL or eWorld or basically whatever. I can type my message once, I can send it, and it will log into all services as necessary, and send the same message to multiple services and it's kind of nice.

M: Did I understand correctly that *Eudora* doesn't do this?

Braddlee: *Eudora* doesn't log into things other than the Internet to check your mail. It only logs into Internet. From *Eudora* you can send to eWorld because [the] user [is] at aol.com or user@eworld.com.

M: I understand, but...

Braddlee: You can send but you can't receive mail from your other accounts. So *Claris E-mailer*'s main benefit is that it will check your mail at other places in your Internet account. Yes sir?

M: [Inaudible]

Braddlee: *Claris E-mailer* will. It's called a "schedule." And basically you can say, "At 6:00 a.m. and 6:00 p.m. Monday through Friday but not on Saturday and Sunday, I want you to log in to this and this and this and check my e-mail." If you have, I don't know, I can't keep track of CompuServe anymore, but it used to be they had prime time and not prime time, so if you wanted to wait until 3:00 a.m. to log in and check your mail it would do that. *Eudora* doesn't do that, so that is the benefit of *Claris E-mailer* that *Eudora* does not have. Also this requires that *Claris E-mailer* is running at the time that, when 3:00 a.m. comes and if you quit the program it can't check the mail for you.

Kevin Savetz: Actually, you have limited scheduling abilities with *Eudora* — you can tell it to check mail every so many minutes.

Braddlee: Right.

Kevin Savetz: But that's not very robust. You can tell *Eudora* to check mail every hundred and twenty minutes but that's really about it.

Braddlee: Right.

M: [Inaudible]

Kevin Savetz: Yes. DOS and [inaudible] does recognize those priority levels and gives at least some limited credence to them. Limited.

Braddlee: Yeah. Something that says it's junk mail, is...

Kevin Savetz: Right. Bulk.

Braddlee: There is the priority information. Lets see if there's any more important questions.

M: [Inaudible]

Braddlee: *Claris E-mail* is a commercial product. It is available from Claris. You can actually download a thirty day fully-functional demonstration — after thirty days it blows up on you because they expect you to pay for it. But yeah, you can try it out. Bet you dollars to doughnuts it's www.claris.com and you can probably find it from there.

Kevin Savetz: And the product *Claris E-mailer/index.html*. It's on page 2 of your handouts.

Braddlee: It's in your handout.

M: [Inaudible]

Braddlee: I believe it's fifty — between \$50 and \$70. I'm sorry, I don't know the exact price, but it's less than \$100 and it's reasonable for what it does.

If there's no more questions about *Claris E-mailer*, this is kind of a different mail program. This is a send-only mail program but it's cute and it's worth talking about. And I think this is a glimpse into the future of the Internet.

This is called *Video Mail*. This is a \$5 shareware program that lets you send audio or video messages attached to your e-mail. This doesn't receive mail and basically it's a very new program. It's just a little hack that lets you take your camera, such as your *Quick Cam*... you can point it at something. The lighting in here is pretty bad but you get an idea of how it will work, and you can record a message.

"Hi from Internet World." Alright, and then we save it. And it thinks about it for a minute, and it gives you a message window so you tell it who it's to. You give it a subject line.

There's not a whole lot of interface here. It's just a kind of a proof of concept and where it's going. You can also type a normal message.

What this will do is it takes that information, that beautiful message that I just created in video, it makes a *QuickTime* movie out of it and it encodes it and it sends it as an attachment using Binhex, I believe. It's a Binhex, basically a Binhex *QuickTime* movie. There's no real magic here — you could do this yourself if you had a *QuickTime* recorder and just attaching a program in *Eudora*. But this is like one little utility that does it all. So you can even preview your movie. And the audio doesn't work, so I probably hooked something up wrong. But you can see there it is.

And then we go "Message: send," and now it will send the text. It will Binhex the file and send it. And this also will do audio-only if you don't have a *Quick Cam* or you just have a microphone, you can send audio messages.

The problem with doing this? Huge files, really big files. A thirty second message will easily eat up half a megabyte, and this is these little black and white things. So if you have a T-1 connection, have ISDN and so does the person you're sending to and they don't mind, go ahead and go for it. Audio takes up about 8K a second so that's not quite as bad although the seconds do add up. A minute's worth of audio takes up a significant amount of time. So now it's sending

the message and if you went back to *Eudora* or *Claris E-mail* it would download the *QuickTime* movie and then we could see the wonderful little movie that I made.

M: This person would receive this over the Internet?

Braddlee: A person with a Windows machine would need two things. First of all, they would need the ability to unBinhex because this is a *Binhex* file that it's actually sending. The next version of *Video Mail* is going to allow you to view [UUencoded], which is something that is much easier to do on Windows. So that will be helpful. And secondly they'll need the ability to play *QuickTime* movies. So they'll need whatever extensions that are necessary in Windows.

Kevin Savetz: *QuickTime* for Windows.

Braddlee: *QuickTime* for Windows. And then they'll be able to see it.

Kevin Savetz: Lets talk a little bit about this guy for just a second.

Braddlee: Oh sure. The piece of hardware here: this is a *Quick Cam* by Connectics. If you've never seen one of these, then obviously you're not on the mailing lists that I am because I get about twelve catalogs a week that advertise this thing. Ninety-nine bucks, black and white, 16 colors, well, 16 shades of black and of gray. It's a cute little quick-and-dirty video camera that you can use for video mail and you can also use for CU-See-Me, which we'll talk about.

M: How many frames per second?

Braddlee: Not very good frames per second-wise. It's like...

Kevin Savetz: Up to fifteen.

Braddlee: Like up to fifteen if you use the smallest window. It uses a serial port as opposed to something faster like a... but the thing is it goes straight into your serial port so you don't need a dedicated video card. You slap it in there and it's quick and dirty and I'm very happy with mine.

And also, keep it away from your dog because mine thinks it's like a tennis ball. So if you see the dog eyeing the top of the computer monitor for hours, [say], "You can't have that." That would be a bad thing. She goes through tennis balls fast enough as it is.

Anyway, *Video Mail* has... it does what I just told you it will do — it has no features other than that. It won't check your mail — it's a one trick pony. Yes sir?

M: Getting back to the camera, *Quick Cam*.

Braddlee: Yeah.

M: Is there a Windows version?

Braddlee: There is — just came out with the Windows version of the *Quick Cam*, also ninety-nine bucks. It slaps in your serial port.

M: Same company?

Braddlee: Same company, Connectics. And they are about to, in the very near future, come up with a color version of the *Quick Cam* which will probably cost a couple hundred dollars. Color data takes up more space than black and white data because you can live with 16 shades of gray but you can't live with 16 colors because it ends up looking like you've got red and blue but there's no white red, so it's kind of ugly. So I have the feeling that using *Video Mail*, your file sizes are going to be even bigger if you go with the color camera.

We'll get back to the *Quick Cam* later when we play with that *CU-SeeMe*.

Actually we're supposed to go until 12:30 — lets take a short break. I think we all need to stretch a little bit and then we'll get into something next.

[Break]

Braddlee: Our next item is going to be *Gopher* and it was up. Now this is this client called *Turbo Gopher*, and I think we'll probably talk a little bit about where *Gopher* is right now in the larger context of the WorldWide Web.

The *Gopher* was the original tool that sort of took the Internet out of the land of the pocket-protector people. The nice thing about *Gopher* is that it gives you a series of hierarchical menus. In this case, *Turbo Gopher* uses folders: events, news and weather. So I can select this folder and go down and take a look at weather and earthquake information.

And what you'll see is down here we have a list of a couple of different items. Up until this point, everything we've been looking at is a list of folders. In this case we have a terminal session for the weather underground. So *Gopher* goes out and it wakes up, Telnet, and so it will talk in-between the different applications.

M: [Inaudible]

Braddlee: Okay. No data available. Lets try BOS. Moderate rain.

Kevin Savetz: Yeah?

Braddlee: Well maybe heavy rain, but moderate is fair. Press return to continue. We can go in, we can take a look at the main menu, see earthquake data. I mean what we're doing here is we've got a terminal session set up with a remote unit's host called Downwind, desktrl.humus.edu which is the Weather Underground, not the Home and Students for a Democratic Society but rather an NSF-sponsored program for providing weather-based information, primarily to K-12 students.

You can see there are a number of things here. We can take a look at the hurricane advisories, although the hurricane season is almost over. The seismology stuff is fairly good. It's a little early for ski conditions but again this isn't really a UNIX tour so we'll get out of here. X to exit.

Now in this case, you'll see this as a text icon so what it's going to do, instead of bringing up a [inaudible] section and showing us another collection of folders, it will actually go and be unable to resolve this name.

Down at the bottom, basically what that means is we probably had what is known as a dead link. *Gopher* is a very simple protocol which is kind of like POP — it's easy to implement. One of the problems with it is that... I go up here and get the attribute information, this is going to show the information that *Gopher*, both the client and what is running on this Mac and on the *Gopher* server that is providing us with information is using as the link to get to the

remote site on the Internet. And my guess is that something about this URL is broken, that it is moved or changed and that's why we can't get to that site.

So let's try something different. Let's try the recent earthquakes. It's connecting, waiting for response, receiving response and what this is, this is actually Finger information. If people are familiar with finger, Finger is a tool for just checking account information on UNIX hosts. There's also a Finger client and demon for Mac which maybe we'll look at later if there's time. But it's essentially... what's happened here is they've taken a very simple tool which is Finger, and in the Plan file which is the file that you can attach to your Finger that will allow you to displace certain information.

Usually we just do account information — the personal stuff. They've put in the recent earthquake information.

M: [Inaudible]

Braddlee: Yeah. You'll notice the *Gopher* is menu-driven which is nice. The *Gopher* came before... pretty much before anyone had ever heard of HTML or Netscape or Mosaic. So this is kind of a predecessor to the WorldWide Web. And of course this is menu-driven and the WorldWide Web is hypertext so you're not locked into the menu driven interface.

This isn't a bad way to do things by any mean, but the *Gopher* has kind of been eclipsed by the WorldWide Web. And *Turbo Gopher* and any *Gopher* client is sort of being eclipsed by Netscape or Mosaic or other Web browsers that can access *Gopher* menus within the same program. So if you can use Netscape to access a *Gopher* menu and you're already in Netscape then that's a benefit that you don't have to run *Turbo Gopher*.

And honestly, it's pretty much the same information either way.

Kevin Savetz: And if you talk to the people at the University of Minnesota who do the *Gopher* development, they have a fairly involved and quite rational set of arguments about why there's still room for *Gopher* in the context of the WorldWide Web based on the idea that there are good reasons to have hierarchical sets of information rather than necessary hypertext. There is room for this, there is room for both in the world.

I think that, even though there is some good technical arguments including the fact that *Gopher* is a much lower overhead protocol than HTTP which does the transport for the WorldWide Web, there is a lot of emotional steps going on here. There's people that are very much emotionally attracted through the *Eclipse*, and naturally the WorldWide Web, and it will be interesting to see if *Gopher* still retains a place in all of this.

Braddlee: There's another tool that the folks at Minnesota are working on in parallel with *Turbo Gopher* and that's called *Gopher VR*. And *Gopher VR* ... the idea behind it is that it will give you a visually navigable *Gopher* menu which is three dimensional — which to me seems to be a somewhat kind of contradiction with the big advantage of *Gopher* — which is that it's been easy to use.

We're not going to show you because apparently, in Kevin's PowerBook, *Gopher VR* blows up rather magnificently.

Kevin Savetz: It's still in beta, is that correct?

Braddlee: It's very, very beta.

Kevin Savetz: From what I understand it's very pretty and you can scroll around... there's these pillars of information — it sounds very nice.

Braddlee: It sounds real nice. It will run on Power Macs reasonably stable. It's dog slow. One of the nice things about *Gopher* is that traditionally it was fairly speedy. You clicked on something and you got to where you were. In *Gopher VR* you had this range of objects. It looks a little bit like Stonehenge so, for example, if we had this list of items, there would be a little Stonehenge monument for each of these items arranged in a circle. They would have different colors and different icon graphic shapes based on what kind of resource they were.

The idea being the shape, color, size are efficient ways to help you navigate to those different lengths. And what you do is you use the mouse pad to sort of zoom around. You can go up above, you can get a 3-D perspective on things.

It's nice, but I haven't really seen anything about it that gave me a sense that it brought about any great ability and usability or efficiency.

Kevin Savetz: I think that any benefit that may have been given to us by *Gopher VR* is probably going to be very readily eclipsed by VRML.

Braddlee: Yeah. And there's a question.

M: Is anybody working on that?

Braddlee: It's the University of Minnesota and it's on the URLs for both *Turbo Gopher* and *Gopher VR* are on the top of page three of your handout.

M: So was it *Gopher* that established the use of URLs?

Kevin Savetz: I don't think so.

Braddlee: No, I think URL's evolved from...

Kevin Savetz: From HTTP which is part of the Web.

Braddlee: Yeah, because at this point, this is just the clearing house for subject-oriented such and such. This certainly does have a URL but when *Gopher* originally came up, we weren't thinking of them as URLs, we were thinking of them as menu items that we could save bookmarks to so this was before the whole URL idea came around.

Kevin Savetz: And one of the things that the *Gopher* does do is it allows you to save bookmarks. You can create a custom menu of your own *Gopher* items and go back again. At this point most people probably prefer to have one set of bookmarks and if you're going to do that, you'd probably want to be doing it in Mosaic or Netscape.

Braddlee: I don't want to bash *Gopher* too much.

Kevin Savetz: No.

Braddlee: It's still useful — it's very easy to use. So I think, especially for educational use...

Kevin Savetz: Right.

Braddlee: You don't have to wait for huge graphics to download. If you click them, it's not like there's all these little hypertext things to click on. This is very easy to navigate. A lot of useful information is out there via *Gopher*.

Kevin Savetz: Yeah.

Braddlee: I don't want to malign it too badly.

M: I've had people tell me that if you do *Gopher* this way — and those are through Netscape — you're going to get to different places and sometimes different information. Is that correct?

Kevin Savetz: I wouldn't see how.

Braddlee: I wouldn't see how. The Netscape *Gopher* ... I don't know if there's a *Gopher* home pitch for Netscape, it may start you off in a different place than the home *Gopher* on University of Minnesota, but assuming you start at the same place, where you go will be the same. But if you start in different places, then you have... basically you're running races in two different directions. Basically you should be able to find the same information, the client that you're using doesn't change the actual information that you're accessing. Question back there?

M: Searching tools?

Kevin Savetz: Yeah. You want to talk about *Veronica* ?

Braddlee: Sure. I'll talk about *Veronica*, although *Veronica* is probably — if *Gopher* is under fire — *Veronica* can pretty much be described as being buried. And I say that with a considerable amount of sorrow because it's actually one of our home projects.

Kevin Savetz: I don't know where to find it honestly.

Braddlee: Oh I'm sorry. I'm in the top menu.

Kevin Savetz: Of home *Gopher* ?

Braddlee: Oh, it may not give you that... maybe because we're coming in from outside. I may have to think about this for a second.

Kevin Savetz: Okay. Well you talk and I'll walk you through it.

Braddlee: Okay. It should have a search.

Kevin Savetz: Here is it. Search office. Okay.

Braddlee: *Veronica*, which stands for, "Very Easy Rodent Oriented Netwide Index to Computerized Archives." I still have this running argument with Steven about which took longer, writing the software or coming up with the acronym.

Veronica, obviously, is kind of a takeoff on *Archie*. There is a kind of a dumb-to-down version of *Veronica* called *Jughead*. The interface that we're looking at right now is actually called Malt Shop. Yes, the lawyers have called. Yes they did work it all out. Find what? Search Gophers by pub, [inaudible] is probably the best place to start.

Kevin Savetz: What are we looking for?

Braddlee: Lets look for *Gopher VR* — probably with a space in between. This is the *Veronica* interface. That's it. You've got that box. And then it will present another... it will create a menu on the fly of any hits that it finds on the topic that we're looking for.

And this is only searching *Gopher* space however. It won't search Web sites, and so if you use InfoSeek or one of the Web's search tools, you have to use that to search Web space. Do any of those do *Veronica* searches as well?

Kevin Savetz: They don't do *Veronica* searches. What they'll do is they'll search for *Gopher* items that are referenced within HTML pages.

Braddlee: The Web search tools can also see Gophers, *Veronica* is kind of dying a slow death because it's not as broad.

Kevin Savetz: *Veronica* is dying a slow death because we haven't been able to raise funding to continue development and broaden it. And actually, slow is probably not even the right word. It's dying a very quick death.

Braddlee: A prolonged, protracted, public, painful death.

Kevin Savetz: Oh, and this is real common. I love this.

Braddlee: And this is, yes, this is your typical *Veronica* response, which means that *Veronica* processes hundreds of thousands of requests a day across those eight or ten servers that you're seeing there. Each of those servers is capable of responding to about ten simultaneous queries which means at any given moment in time there are about a total of a hundred and twenty-five different *Veronica* searches that can be done at any given moment worldwide.

Kevin Savetz: And there are what, twenty million people on the Internet?

Braddlee: Yeah, exactly. If anyone has got \$30,000 that we can get a Sparc... twenty and set some stuff up and we'd be happy to give you your own *Veronica* server and name it after you, but right now that's... yeah.

So, the other nice thing that they've done — we talked a little bit earlier about the Swiss Army Knife versus the discreet tools concept. The folks at Minnesota are working with the discreet tools concept and what they've done is, for example, we saw earlier when we hit a Telnet reference, rather than trying to do it itself, go for handing that off to NCSA Telnet. It will do that also with WAIS requests, it will hand it off to MacWAIS. If it has an HTML reference, an HTTP reference, it will hand it off to MacWeb or if you choose Netscape, it will hand it off to Netscape. So what they're really trying to say is it's like, well, you have a *Gopher* client and you'll have a WAIS client, and each of these things will be smaller, independent applications that will do their particular thing well. Netscape being a commercial company says we want to do it all for you. We want to give you the single tool.

Kevin Savetz: And which is better depends on how you work.

Braddlee: Yeah.

Kevin Savetz: If you want discreet tools, you can really customize how you work with your computer, but you've got to install more and update more information. If you want to have one piece of software that does it all and you don't want to deal with a bunch of little things, you can do that as well.

M: Could you explain again what you said a few minutes earlier about how the Web browsers treat the *Gopher* ?

Braddlee: Sure. In fact, let me... I'll launch a Web browser and you'll see, if we have a Netscape running.

Kevin Savetz: You know the *Gopher* ... scs.unr.edu.

Braddlee: So basically, we're going to bring up a *Gopher* menu here and you'll see that once it comes up, it more or less looks like it does in the other program — it looks a little more hypertext, but basically it's just a menu. And if you want more information... let's go to the place where you've gone before here. "Search all *Gophers*" is a menu that we've seen before.

M: Now if I wanted to use one of the search engines from the Netscape or another program, would it search for that key word within the *Gophers*?

Braddlee: No. What it's going to do is... see that's one of the problems right now, is that — at least it's my understanding of it — none of the Web based search tools also look at *Gopher* space except where *Gopher* references occur within HTML documents so to sort of rephrase that, if you have a Web document and it has a *Gopher* URL as part of that page, then Info Seek or Lycos will come through and grab that *Gopher* reference, but it doesn't go and poll each of the individual 6,500 *Gopher* servers that are still out there in the universe in the same way that *Veronica* does.

M: So essentially, for the future, for *Gopher* sites to survive, they need to subscribe to some Web pages?

Kevin Savetz: You mean linked from some Web base?

Braddlee: That's right. Or some sort of miracle has to happen so that *Veronica* can survive and continue to be a viable tool for indexing that and seek better.

Kevin Savetz: And frankly I don't see any good reason why Info Seek or Webcrawler or one of those tools can't also link through *Veronica* — layer on top of it. It's just something no one has done yet.

Braddlee: Right.

Kevin Savetz: If you're good at programming, please be my guest.

Braddlee: Yeah, exactly. And there's no reason you can't... I mean I'm sure Steven would be happy, and the University would be happy to license the hooks. Or frankly, people could just go and write their own.

I think one of the things that I try to emphasize with people is that a lot of folks will go to InfoSeek, they'll do a search, they'll go to Yahoo, they'll look in the subject directories, and if they don't see something in one of those two places, they assume it does not exist on the Net. And it's really important to realize that neither of those resources — as good as they are — are encyclopedic, and that you need multiple search strategies and multiple tactics to find things on the Internet.

Kevin Savetz: One day you'll be able to buy a software agent that you'll install on your Macintosh and you will say to it — hopefully just by speaking at your Macintosh — “Find me everything about such and such,” and it will search everywhere it knows and bring it to you in one little place. But that's just my dream and isn't reality. But it's probably, honestly, coming in the future. I think that's about it for *Gopher*. You want to go with low-level tools or do you want to go with Web browsers?

Braddlee: Lets go to the low-level tools.

Kevin Savetz: Okay.

Braddlee: Because I think it's important that people know how to plug in. Okay. We're going to switch gears for a moment and talk about low-level tools, the actual programs that put your Mac on the Internet. Last year we talked about those things first thing but it's not the most exciting topic and we don't want to start you off by boring you so now that you're interested, we're going to bore you a little bit.

Kevin Savetz: We started off with a big splash by showing you Telnet.

Braddlee: Yeah.

Kevin Savetz: Just quickly... I'm sorry.

Braddlee: Sure, go ahead.

Kevin Savetz: Is anybody not going to be here this afternoon? Okay, so we really do want to show... to make sure that Netscape does get into this.

Braddlee: This is what we promise, so we'll do that.

The Internet uses protocols called TCP/IP to move information around, Transmission Control Protocol/Internet Protocol. I'm not going to tell you how it works. There are some other sessions on that and it's frightening stuff anyhow. But your Macintosh needs to know how to move packets around with TCP/IP, and the program to do that is called MacTCP — it's a control panel... it's one of the few things that we're showing you today that is not freeware or shareware.

This is commercial software available from Apple Computer. If you buy it from Apple's Developer Toolkit Company, they'll charge you about \$75 for it. The better way to get it if you don't have it [because] you need it — I mean there's absolutely no way around that, is you go

out and buy the book *Internet Starter Kit* for Macintosh by Adam Engst. It's an excellent book. It's published by Heyden and beside the fact that it's a great book, it comes with a disk filled with good stuff including MacTCP. And the book is only \$35 or something like that. \$29.99 or something good. So it's less than the actual cost of the software.

M: Adam Engst?

Braddlee: Adam Engst, E-n-g-s-t.

Kevin Savetz: And maybe while we're talking about Adam, talk about the *Tidbits Newsletter* for just a second?

Braddlee: Go ahead.

M: I'm sorry. Doesn't that come with... if you were to buy a Mac tomorrow, wouldn't that come with it?

Braddlee: Yes. System 7.5 allegedly comes pre-installed with MacTCP. I haven't proven that myself, but that's what I hear.

Kevin Savetz: Yes, it does. Adam — in addition to writing *Internet for Macintosh* — has a really excellent Internet based newsletter about Macintosh stuff including a lot of focus on Macintosh Internet tools. And it's called *Tidbits*. And what we can do is...

Braddlee: It's tidbits.com.

Kevin Savetz: Right. So I was thinking about the mailer for it. Keep talking. I'll find it.

Braddlee: He has his own FTP site which is FTP tidbits.com but it is something that if you get that book or even if you don't get the book you may want to subscribe to.

Kevin Savetz: And it's a free newsletter delivered by electronic mail.

Braddlee: Yeah. And it comes just often enough to be useful and not so often that it's annoying.

Kevin Savetz: You can read it on-line or on the Web or by E-mail. The quickest way to get the information is to go to <http://tidbits.com> and then you can get information on how to subscribe to it. If you're not on the Web yet, come up here and we'll give you the e-mail address later. But if you're not on the Web yet, shame on you. Okay. Enough about *Tidbits*.

Braddlee: So we've got MacTCP which is this really geekie. There's this really geekie control panel, want to see something frightening? Basically this where you tell it all the low level information. It says hey, I want you to be on the Internet and I want you to talk.

Here is the router we're talking to, this is where we're getting domain name server information, this is our subnet mask. This is all a bunch of stuff that you can set once, your Internet provider will give you the information and hopefully it will work and you can get logged in.

And you need all of this stuff. None of it is optional. For example, the gateway address, that router, that is how we get up off the local area network after the rest of the Internet. That

is not optional. Domain name service, if you've been using a lot of addresses like tidbits.com. All of those names that we used on the Internet, that people like, are mapped across a series of number, like 134197.25.97 which is the unique numerical address of the Mac that sits on my desk in Reno which is also known as braddlee.scs.unr.edu.

Kevin Savetz: And it's a heck of a lot easier for us to remember the words than it is the numbers.

Braddlee: Right.

Kevin Savetz: So DNS, Domain Name Servers, translate the name to the numbers, something that we understand to something the computer can understand a little bit better.

Braddlee: Right, exactly. And there are things that are just not optional stuff, you've got to have them. Your net service provider, whoever manages your local network will know these things. If they don't, drop them immediately. And you basically just follow the instructions.

Kevin Savetz: Right. Follow the gateway number, into the gateway, put the domain name service and the domain name.

Braddlee: Depending on how you access. So that's MacTCP. You set it up, hopefully it works, you forget about it. Depending on how you access the Internet, you may need one or two other tools. Currently, if you're at work and you have an Internet connection, you might be on the Ethernet. This wire is basically just the Internet and plugs into my Ethernet and goes into the back of my Mac. MacTCP is all I need. I set it up correctly.

However, if you're dialing in — a lot of people access the Internet via modem, they have a 14.4 or whatever modem sitting on their desk and they're dialing into the Internet — you need one other tool. And actually there are two tools you can do it with, but you need one of them. One is MacPPP which stands for Point-to-Point Protocol. And the other one is called MacSLIP. I'll bring up PPP if I can find it — here it is.

This is another low level protocol which actually takes the TCP/IP information and translates it to PPP information so that you Mac can talk to it. It's just another low-level tool. You don't have to really understand how it works. You just have to have it for it to work.

Kevin Savetz: And this is only if you're connecting over a phone line — if you have a direct Internet connection, this doesn't apply to you.

Braddlee: Right. If you log in with a modem, this is... you probably use this program because this is actually the program with the button that you press to log in. You press the Open button and your modem dials in and gets you connected and that sort of thing. It has all sorts of configuration options, the phone number you want to dial, your modem and net string.

Kevin Savetz: What is your credit card number?

Braddlee: There is my calling card number if you need it. Your connect script with your password and all that good stuff.

Kevin Savetz: One of the things that would be nice for it to do would be to encrypt both some of these phone numbers and passwords, particularly to people who do stuff like both of us do, to travel with PowerBooks. It doesn't do that. It's a little bit of a security problem.

Braddlee: Yeah. Basically, anyone could sit down at your Mac and find out what your password is. Actually there is a way around that if you're... but usually not.

So this is just another one of the low-levels tools. You set it up once, you run it, you hit Open, it talks to MacTCP for you. It just does some of the dirty work to get you connected.

M: [Inaudible]

Braddlee: No, the MacPPP and MacSLIP are both freeware that you can download off the Internet.

Kevin Savetz: Once you've gotten your connection.

Braddlee: Once you've gotten your connection. Or you can buy that book by Adam Engst and it includes it as well.

Whether you SLIP or PPP... I'm not sure if I actually have SLIP on here. I may not. They both do the same thing — they connect you to the Internet using either the SLIP or the Point-to-Point Protocol.

The one you will use, your Internet service provider will tell you. They will say, we support PPP or we support SLIP. You don't argue with them. You set up the program and you get on with your life.

If they give you a choice, take PPP over SLIP. It's a little bit faster, a tiny bit better. But if you have SLIP, not PPP, don't worry about. You have a question back there?

M: [Inaudible]

Kevin Savetz: I don't know very many people that are actually offering just SLIP anymore.

Braddlee: No, me neither.

Kevin Savetz: Yeah. There's probably just somebody out there.

Braddlee: So anyway, those are the low-level tools and incredibly boring, so lets take any more questions and then get onto Netscape, or [inaudible]. Yes sir?

M: [Inaudible]

Braddlee: It should come with a... if you buy a fax modem, does it come with the software? Probably not. It may. There's no telling what is bundled with the modem, but the two things you need, MacPPP and MacTCP — I wouldn't count on it. And you probably need to find them from another source.

Okay. Wake up. Now we're talking about Web browsers. If you haven't heard of the WorldWide Web, the door is back there. What's that? Believe it or not, there are other Web browsers other than Netscape. There are, in fact, quite a few. And we're going to look at a couple versions of Netscape and a couple of other Web browsers.

The Web browser that made the WorldWide Web what it is, is called NCSA Mosaic. And NCSA Mosaic is a good program. Frankly though, when Netscape came out it was — Mosaic was completely eclipsed by Netscape because it's a little bit more powerful and it has some features that Mosaic doesn't have.

Kevin Savetz: And some of the history behind that is that a guy named Mark Andreessen who is at the University of Illinois and was working as basically a student programmer for the National Service for Computing Applications, the same people that did NCSA Telnet. He and some other folks wrote the original version of Mosaic, and I suppose somewhere after the first million copies of Mosaic went out the door, he probably wondered why he was making \$8 an hour.

He joined forces with Jim Clark who was the former CEO of Silicon Graphics, the high-end workstation people that do the computers that get used for things like *Jurassic Park*. Then they formed Netscape as a company and rewrote Mosaic from the ground up with more people, more money and basically they pretty much whooshed by Mosaic at this point.

Braddlee: So this is NCSA Mosaic. This is the most recent version, version 2.something.something else.

And we're going to... you're going to be able to see that no matter which browser or client you're using, it's still the Web. You've got something you can click on, which is usually blue underlined but not necessarily.

You've got your graphics, and you can scroll around and look at the absolutely... (it's still getting the information). And if you want more information about something, it's hypertexted — you can click on it and it will bring up another page.

Mosaic... I'm groaning at it — Mosaic feels slower than Netscape. Honestly, I use Netscape everyday. Mosaic hasn't, as I said, hasn't quite kept up the pace with Netscape. It's a little bit slower. You load a page and it takes a little bit longer for all the graphics and everything to come up. However, it's still a pretty popular browser and they're still actively working on it. And by no means have they given up the race. I think it's still a viable browser, although not my personal favorite.

And something else, too, to keep in mind is NCSA's Mosaic is free for anybody — whether you're commercial, governmental or educational. There are some restrictions on the Netscape free license.

Kevin Savetz: Right. Netscape is a commercial product that you can buy for about \$50. There is a free version available, however, the license agreement says that it's only available for educational and non-personal use for thirty days. Nobody ever does that. Everyone just downloads it and uses it forever, but we are not condoning this activity and it is a product that should be paid for if you're going to use it — even though nobody ever does. Although if you pay for it, you get support.

Braddlee: If you pay for it and you're having trouble with it, you can call up and whine. Calling NCSA and whining about Mosaic will not get you very far. Yeah?

M: What's the difference between NCSA Mosaic and [inaudible].

Braddlee: What happens is NCSA has licensed the original source code for Mosaic to a number of companies, I think Quarterdeck and Spry and a couple... there's not a unique license for it, a number of companies have purchased that. What they've done is they've gone in and they've

rewritten the Mosaic code to make it faster, to make it support more extensions, to do a number of things. Since our focus has primarily been on the free or shareware tools, we're not going to go... there are a bunch of different enhanced MosaiCs.

Kevin Savetz: I'll bring up one of them I happen to have here.

Braddlee: Great, good.

Kevin Savetz: Sometimes you'll buy a book and it will come bundled with an enhanced Mosaic. O'Reilly and Associates has a book called *Cruising the Web with Macintosh* or *Surfing the Web with Macintosh* or something like that. And it comes bundled with this particular version of enhanced Mosaic. In its heart, it's still NCSA Mosaic but they sped it up a little bit, they added some features and kind of made it a little bit spiffier.

Braddlee: You get a different home page.

Kevin Savetz: Yeah, a different home page. I'm trying to bring up another, so you can see — it's still the Web. And you can't get enhanced Mosaic without paying for it. Generally it involves buying a book or some other product that comes with it.

Braddlee: One of the things about Netscape that has sort of helped to keep it out in front is that Netscape has been fairly aggressive about developing new extensions to the HTML standards — Net things that the people who are doing Web page development like and grab onto and use fairly quickly even though they're not necessarily ratified standards. And this kind of puts the folks who are doing other Web browsers into a difficult position because Netscape will go out and promulgate something and they have to wait until their next release version to incorporate it into their browser. So they're always — almost by definition — one step behind some of the stuff that Netscape is doing because Netscape dominates so much of the market. They're kind of getting to [be] defacto a lot of the standards.

Kevin Savetz: I'd like to give an example of that.

Braddlee: Good.

Kevin Savetz: We're going to bring up a page in Netscape which is Netscape enhanced for your pleasure, and while that's working I'm going to bring up the same page in Enhanced NCSA Mosaic. Open URL, all right. And it used to be things as basic as centering wouldn't work. And now, I mean tables where you have raised tables, and a number of other things are just and the frames that are coming out.

Braddlee: Here is a Web page from my Internet service provider. This is like that, what is different between these two pictures came. So notice Internet, and you can see the text, there's some bold and there's some links and, okay, fairly plain, certainly readable.

Here's Netscape's version. Same information, same Web page, same HTML code. We've got the green background, we've got the funky... the great, huge text with the huge letters. And frankly, it's just a lot more appealing. It's a lot prettier to look at. But it's the same information and frankly, eventually I'm sure the other MosaiCs will catch up.

But Netscape, although it does a fine job, is kind of... leads the pack because it makes up its own rules and waits for a stamp of approval later.

M: I read that they have formally announced that they are going to start going through the proper channels.

Braddlee: Well, they kind of always, sort of have done. I mean what they do is they go in and propose it as a standard and they incorporate it in their browser. And there's absolutely nothing wrong with that. That's perfectly fair and legitimate and no one is saying that anyone has to use those codes. But what is happening is that out in the marketplace, the codes that they're developing are the things that people want to use. They're responding to the market need and the standards aren't really keeping up.

No, everything that they do is open. And everything that they're doing fits in. I don't want to propose... say that they're doing anything unfair. They're not. They're just being...

Kevin Savetz: They're being aggressive.

Braddlee: Yeah. They're aggressively trying to move things forward because they care about it as a medium. And also it's in their self-interest to a certain extent.

If somebody else had 60% of the market share, they could also help define standards in the same way. It will be interesting to see how this plays out, whether it ends up in the long term being a healthy thing or whether we're making a marriage now that we will regret later.

So we're in Netscape so we might as well talk about Netscape now. I mean not that we haven't been.

As I said, Netscape is a commercial program, about fifty bucks, you can get it for free if you're an educational or as a trial basis.

The current version is 2.0. It's still in Beta. If you're scared of Beta products, you can use version 1.1. 2.0 is allegedly adding some features that... some of which are available for the Windows Netscape but not on the Macintosh as is so often the case, we need to wait a little bit longer than Windows users.

Netscape will allow... have an interface for Java which we'll talk about in the second half, as well as adding an enhanced e-mail program so if you want to send e-mail from Netscape in one place you can do that as well as some additional HTML tags and some other things.

Kevin Savetz: Yeah. Right. An allegedly enhanced news reader.

Braddlee: On the Beta version of this, Kevin says he has been running this quite happily in his PowerBook for the last week or two. It just came out quite recently.

When I installed this in my PowerBook, it blew up. I've looked at it a number of different ways, installed it. There is a thing called [Defrost] which is out which is a freeware patch to address some MacTCP problems that Netscape 2.0 B-1 is having.

I've found some things that are broken in the news reader and in the mail, even when I use it on my desktop Mac so my call on this would be that this Beta version is still pretty Beta. And if you're adventurous and you like to be out on the edge and see things that are going on, great, go for it. But don't throw away your copy of 1.1 which is a stable release version.

M: Can you leave them both on the machine simultaneously?

Kevin Savetz: Yes. You can leave them both on the machine simultaneously but you can't run them both simultaneously. Frankly, the coolest new thing in Netscape which is supposed to be Java isn't there yet, so I don't know, download if you want to but don't expect...

M: [Inaudible]

Kevin Savetz: No, it should not. Back there?

M: [Inaudible]

Kevin Savetz: I'm sorry?

M: [Inaudible]

Kevin Savetz: Right. I don't know anything about *Open Transport*.

Braddlee: I guess what I know about *Open Transport* is that *Open Transport* is out. It certainly does all the functions the MacTCP does. The problem is that there have been a number of problems with it working with existing Internet applications.

For example, CU-SeeMe does not work with open transport. A number of other things won't work with open transport. There was Guy Kawasaki's list just announced day before yesterday that there was an interim release of *Open Transport* to address some of those problems, what they described as the most critical.

I'm kind of waiting on *Open Transport* until the next real release version or when my 8500 comes in and I will probably start running it on my 8500. I'm back ordered until like the next solstice. So I assume that by the time the 8500 arrives, that new version of *Open Transport* will arrive and I'll get them both about the same time and then I'll start digging into it.

M: [Inaudible]

Braddlee: Right. I would... if it was today, if it was my Mac and I didn't have the job that I have, I would stick with MacTCP. Because of the job that I have, I would use the *Open Transport* but I have a feeling I would be spending a lot of time swearing at it.

I've talked to folks that are having to support it and they're not real happy about it. I think it's going to be a really good product when it's finished. But it's [not] being released, it's not a finished product.

And to be fair, the earliest versions of MacTCP had some pretty ugly things about them too. So, it's interesting but I don't think it's quite ready for prime time. I saw another question back there?

M: [Inaudible]

Braddlee: Okay. I don't know what else there is to say about Netscape.

Kevin Savetz: Show the mail?

Braddlee: Oh sure. I can actually... we can't show news actually which is [interesting].

Kevin Savetz: Well actually, hold on, we might go talk to the server over at Netscape. Yes?

M: [Inaudible]

Braddlee: All right. One of the things about the Netscape browser that I don't believe is true about Mosaic, and Kevin correct me if I'm lying to you, is that when Netscape was built it was really designed as being a commercial tool. At the point it came out, everybody had already kind of caught on to the fact that having hypermedia and having multimedia on the Internet, as a network environment was a big tool for marketers and for distribution of information.

So security has been built into Netscape in a number of levels, both at the level of being able to see, for example, the broken key down at the bottom left hand side of the screen indicates that you're not talking to a secure server meaning that you can't be absolutely positively certain that the server that you're talking to is the server it is purporting to be.

Also Netscape supports the secure transactions. And there have been a couple of concerns about that, one of which is some guys at Berkeley had found a back door to break some of the security features. That resulted in the release of the 1.12 version of Netscape and a lot of, sort of, hooray, that's a very minor bug.

The other thing which is probably more interesting is a guy in France recently broke the 40-bit export version of the Netscape transaction keys. What that means is there are... the U.S. right now has some, and we'll talk about this a little bit this afternoon, has some significant issues about the licensing and exporting of encryption software for secure interactions.

The export software, if I recall correctly, is limited to a 40-bit key length which is breakable. A gentleman in France recently proved that by lining up a super computer and about eight other toys and spending a week or two breaking a single Netscape key, a 40-bit single Netscape session key.

So, in other words, it took more than half a dozen computers more than a week to break what would be the equivalent of a single credit card. So it's not very practical but it can be done with the very small key lengths that people are restricted to exporting.

And within the United States, the key length is 128 bits and that's significantly more secure but it really is... it's a policy question, it's a commercial question., there is some real issues about doing international business using these sorts of tools right now.

Kevin Savetz: This is what happens when you request a secure document, is it okay? You'll notice that the key here is not locked. Actually now, this is Wells Fargo, my bank. You can go in there and see that this service lets you find out what your checking balance is, whether check number 1234 has cleared, but, you don't want those packets going unencrypted on the Internet, so this is encrypted and I can feel relatively secure that casual snoops won't be able to find out that I'm broke.

Braddlee: Or even fairly dedicated snoops at this point.

Kevin Savetz: Yeah right. Yes sir?

M: [Inaudible]

Braddlee: Yes. Well the server... Netscape uses both of the two different users.

Kevin Savetz: It uses SSL and SHTTP.

Braddlee: There are two different ways to be secure, to do secure HTTP. One is called Secure Sockets Layer or SSL and the other is called Secure HTTP, two different protocols for doing about the same thing.

A Netscape client can handle both of them. Allegedly anyone can write a server, a Web server, which can use those protocols. The biggie though, the one that everybody uses, the one that a lot of people trust is Netscape server which is a \$5,000 piece of software called Netscape, Server which you can use to move secure information.

Alleged... theoretically any browser can have these functions and any server can have these secure functions, although there aren't a whole lot of them for the Mac at this point.

Kevin Savetz: The MacWeb supports SHTTP. It doesn't support SSL. Netscape supports both of them. As far as Web, MacWeb servers, the Web Star Server which is the commercial version of MacHTTP is going to, by next spring, support both [inaudible] and SHTTP, at least from what I understood from talking to them the other day. Yeah?

M: [Inaudible]

Braddlee: It's actually a separate Web server, for instance, that Wells Fargo is running. They actually have two Web servers. They have the not encrypted one, the not secure one and then they have the secure one. And anything that runs on the port of that secure server is by default secure.

So basically, they have a separate machine and whenever anything goes to that machine it is secure. It's not like a [inaudible].

M: Well if you wanted to make a document secure, you have to basically [inaudible]?

Braddlee: Yes. That is correct because your system needs to be running a server which does security which generally costs bucks and ISP, servers who purchase that are probably going to keep that so that you have to pay them a little extra because it's an expensive product, the software.

Okay.

M: [Inaudible]

Braddlee: Yes. There is another Web browser which is called... which you briefly mentioned called MacWeb. As far as I know, it hasn't been updated in ages.

Kevin Savetz: Ages. Meaning at least ten or twelve months.

Braddlee: Yeah. No. It hasn't been updated in a long time and frankly it's... I will load it up just so that you can say that you've seen it, but it is out of date. Version 1.0 Alpha 3 came out like a year ago, and it's not been updated. The program didn't stay with the times. There are better programs for browsing the Web.

The benefit of this program, really the best one, is that it's a very small program and if you're limited on memory, MacWeb actually does an okay job. But you're not going to get the pretty Netscape enhanced graphics or anything. But it fits into a small memory space if you're tight.

Kevin Savetz: The lost generation of Web browsers.

M: Does *Lynx* run on Mac?

Braddlee: No. *Lynx* is a text-only Web browser mainly for UNIX if you don't have a graphical interface. And there is no version of *Lynx* for the Mac, which is really, I don't think, any major loss.

M: It is for people who can't see.

Braddlee: For people who can't see, you can log into... basically log into a UNIX system and use *Lynx* from there.

Kevin Savetz: And the screen readers you were talking about visually impaired folks who need readers. Yes. No that's...

M: It's a major loss.

Braddlee: There are utilities that will work with screen readers for the Macintosh which will work with any program, so you could use Netscape and a screen reader or whatever.

M: What's the statistical breakdown? Everybody says 80%, 75% to 80% of people use Netscape.

Braddlee: That's what I hear.

M: What about the other 20%? Have you read the most recent statistics?

Braddlee: Well I have a feeling that they're scattered among the other, whatever is left. It used to be there was Netscape and then NCSA Mosaic and then 1% was everything else. But I think right now, the other 20 to 25% is everything else.

Kevin Savetz: I guess AOL.

Braddlee: The AOL Web browser, right.

Kevin Savetz: It's used by a lot of people. And then there are other things.

M: I heard there was a pretty large, there's a surprisingly large number of people still using *Lynx*?

Braddlee: Well sure. I mean, for example, in our environment, in higher education, we're in the process... we were just getting to the point where we're able to offer PPP and dial-up Internet connections to our students. Some of these cost a half million dollars to bring about. So those students currently have regular analog dial-up connections and they use Pine, the UNIX program for e-mail. They use the UNIX version of *Gopher*, they use Ten, the UNIX news reader and they use *Lynx* to do their WorldWide Web access.

Kevin Savetz: Here's what the Web looks like if you're using *Lynx*. Same information, less pretty, but it does the job.

Braddlee: And yeah. And *Lynx* has continued... *Lynx* actually is keeping up. *Lynx* does tables, *Lynx* does forms, there they're making an effort to keep *Lynx* current with the standards.

M: [Inaudible]

Braddlee: Most of those will work in *Lynx*. They're behind but they're trying to keep up. I'm trying to think of something that would be...

Kevin Savetz: I'm bringing up that North Coast Internet page again. While that's loading up, we'll take a question over here.

M: [Inaudible]

Kevin Savetz: Interesting.

Braddlee: In 2.0 or 1.2?

M: [Inaudible]

Braddlee: I almost never have to turn off graphics, I have to admit. I did it last night and it was almost painful.

M: [Inaudible]

Braddlee: Yeah, it is. I don't know. Honestly, I don't know the answer to that.

Kevin Savetz: Here's the same Web page in *Lynx*. This doesn't have any tables on it. Off the top of my head, I can't think of any pages with tables but it's not centering the stuff, but other than that, it's handling it relatively well I guess.

M: What if they gave you a second table?

Kevin Savetz: Hey, I'll try anything once.

We're going to start wrapping up. It's time for the break.

Braddlee: While you're looking, I'll talk about something else. Helper applications.

Netscape does a lot of things on its own but it doesn't do everything. A lot of pages are now being enhanced with sound, they're being enhanced with video clips, they're being enhanced with other neat multimedia things. One of the things you'll still need [inaudible] supporting more and more are those things internally is you'll want a selection of helper applications.

QuickTime comes with the Mac. You'll want that. That will be a *QuickTime* video player. There is JPEG View, JPEG images at a higher, clearer resolution than Netscape's internal GIF and JPEG tools.

Another net thing that it should have would be *Reel Audio*. I don't know if we've got *Reel Audio* at this show. *Reel Audio* allows you to have not streaming video, not live video... I'm sorry, not live audio but rather stored audio that can then be downloaded. But the neat thing about *Reel Audio* is it allows you to play it back right after you've clicked on the link rather than having to wait for the whole audio file to download.

The compromise in that is that the audio quality is bordering on tragic but if you like AM radio from the 60's you'll really love the fidelity of *Reel Audio*. But again, it's kind of a proof of

concept, they're taking it forward. I was talking to them and their next version is going to support 16-bit audio which is sort of near-CD quality sound.

Kevin Savetz: If you have the bandwidth to support it.

Braddlee: If you've got a bandwidth to support it. It will require that... right now *Reel Audio* requires 14.4K connection. The new version will require 28.8 connection, minimum, to work, to get your performance.

Kevin Savetz: We brought up a form, this is at L.L. Bean using *Lynx*. So it's a reasonable form. You can fill it out. It works in Netscape, it works in *Lynx*. It slices, it dices. That's it. Yeah?

M: [Inaudible]

Braddlee: *eWorld* is the on-line service, you mean? *eWorld* is an on-line service, like America Online. It is... it has a Web browser so basically if you don't have any other Internet connection, you can use *eWorld* or America Online to access the Internet with their Web browser.

Unfortunately, you cannot use any other browser so if you don't like theirs, you can't use Netscape instead. You're stuck. But it's a good way to access the Internet if you don't have a local ISP, if you're out in the boonies or something like that.

I'll bring up *eWorld* just so you can see it?

M: [Inaudible]

Braddlee: I don't believe so. I have used AOL's browser which is... you didn't hear this from me, but it's crap. They're coming out with a new version next year. It will be better, yadda, yadda, yadda.

I have not used the *eWorld* browser myself.

M: [Inaudible]

Braddlee: If you're using AOL or *eWorld*, you cannot use any other browsers other than theirs, on the Macintosh.

M: [Inaudible]

Braddlee: Only for Windows. Windows users can. Macintosh users cannot. And it's not easy, but it's doable.

M: [Inaudible]

Braddlee: About Microsoft *Word* being a browser... I heard about that. I heard Microsoft *Word* is going to be a browser and... as well as being a word processor. And also I heard about some other product, oh Quicken is going to have a browser in it.

I don't know why. I think it's stupid. I think Microsoft *Word* should be the best damned word processor that Microsoft can make it and Quicken should be the best darned financial program there is and I don't need fifteen Web browsers, but I'm going to have them.

I think [its time for a break.]

[Break]

Braddlee: ... such as Telnet, FTP Tools, and Web browsers and also some of the low level tools like MacTCP and MacPPP.

In this part, we're going to look at some of the fun stuff, the cutting edge multimedia toys such as audio conferencing applications, video conferencing application and other goodies.

A lot of this stuff is really on the cutting edge. We're going to be showing you a lot of Beta software, software that is still under development. It could crash on you.

Kevin Savetz: I think it's probably fairly comfortable saying at least something will... at least one thing will crash.

Braddlee: Yeah. In the next two and a half hours, we'll get something to crash for you.

Kevin Savetz: So we can start a pool on when the first crash will happen if you want to take bets we'll handle that for you. I am from Reno. We know how to do these things.

Braddlee: A lot of this stuff is cutting edge. It's new, it's in Beta, so if you're scared of Beta software you might not want to try some of this stuff.

Also, a couple of times during the next two and half hours we're going to say, not here yet, real soon now. And that's sort of life on the cutting edge and also life with a Macintosh because if something is going to be cutting edge sometimes they develop it for Windows first and import it to the Mac, and that means we have to wait.

Kevin Savetz: Although some of the things we're going to see are Mac only.

Braddlee: That's true. We are going to start with audio conferencing applications which is a relatively new thing. There was no, there was really no... hardly any talk about this at the last Internet World six months ago. There was one program for the Mac called *Maven* which was buggy and crashed a lot. Now there is *Maven* which is currently today buggy and crashes a little.

And there are actually two or three other programs for audio conferencing on the Mac. It used to be you were talking to people on the Internet involved bringing up a talk window and typing, chatting "Hi, how are you?" And they would say "I am fine." And it was just text on the screen.

Internet tools have progressed very rapidly towards multimedia, and now if you want to, you can use a variety of programs to actually have a microphone, have a speaker on your Mac and say "Hi, how are you." And the person can hear you in more or less real time, hear your voice, and you can speak to one another. And there are a variety of programs for doing that.

Kevin Savetz: And one of the nice things about doing this on the Mac platform is that Mac has full duplex audio built in.

Braddlee: Most Mac models have that. Most Macs. True. If you bought it in the last year and a half to two years, with the exception of a couple of PowerBooks, they have full duplex audio.

Kevin Savetz: Which means you can talk and listen at the same time, much like on the phone.

Braddlee: Right. And that the support for multimedia is much better. Things tend to run better and if you guys are... any of you guys have to do multimedia on your Windows, installing, configuring cards, getting things to work, getting things to play nice with each other, is a lot more trouble.

I mean what we're doing here, I wouldn't even want to think about trying to do a live demo with as many different applications as we were bringing in today. Where we kind of like schlepped a lot of them over... some of them over from my hard drive to Kevin's hard drive and just kind of put it all together. *NetPhone* ?

Kevin Savetz: I was... do you have a *Maven* reflector that we can use?

Braddlee: No, I don't know.

Kevin Savetz: So have you seen any reflector that... ?

Braddlee: Yeah. We can point to.

Kevin Savetz: You do that and I'll explain.

Braddlee: Okay.

Kevin Savetz: The first one we're going to work is called *Maven*. It's been out the longest. *Maven* is freeware and it's a program that will let you chat with other people in real time. It lacks some of the nifty features of *NetPhone* and *PGP Phone*. We'll show you what those are. But this is a basic, relatively stable audio conferencing program so you can meet up with other people and chat with them.

If you're looking to chat with a specific person, who is also running *Maven*, you can... and you know the IP address of their Macintosh, you can type it in and assuming that they have *Maven* running, you can chat with them in real time.

Maven also is compatible with some other applications. It's really one of the most cross-platform-compatible audio conferencing applications that there are which means that if you want to talk to someone who doesn't have *Maven* but they have *CU-SeeMe* which we'll look at in a little while, you can talk with *CU-SeeMe* and if someone has *NetPhone* this will talk platform the *NetPhone* as well.

It should also talk to *CU-SeeMe* on Windows although the last I heard, the Windows version of *CU-SeeMe* could play audio but could not encode audio, so as soon as it does you'll be able to actually have a cross-platform-conversation with your Windows loser buddies that you may have.

Kevin Savetz: Nobody home so far.

Braddlee: Nobody home so far.

Maven... what we're trying to do now is connect to a reflector which is a place, a public server, where people can connect basically to chat with strangers. It's like a pub. You can go into a bar and then find someone interesting to talk to.

In *NetPhone* it's called a net pub. In *Maven*, in *CU-SeeMe*, it's called a reflector. And getting into reflectors can be a dubious proposition so we're trying to do that now.

Maven's primary disadvantage... actually I could think of two. One is that it crashes a little bit more than *NetPhone*. And number two is that it requires kind of a lot of bandwidth.

NetPhone will work under 14.4 kilobits per second so if you have a modem at home you can use *NetPhone* to do audio conferencing.

Maven works a lot better with 28.8, with 14.4 it sounds like that. And that's not very useful. It's fun to play with but not useful for getting work done. At 28.8 *Maven* does a lot better.

M: Where do you pull it down from?

Braddlee: We have... you didn't get it, but we have a handout which lists where to get everything that we've talked about. And you are offered that which I will give you right away.

M: [Inaudible]

Braddlee: Have you ever used *Maven* from behind a firewall, a proxy or... I think that would be real dubious because I'm not sure what port. The thing about this is you'd have to have it... it's going to use a specific port, and to be honest, I don't know what the port number is for that. So what you'd have to do is you'd have to have the firewall administrator open up that port, and firewall administrators don't usually like to open up ports without some sort of compelling [reason] why.

Kevin Savetz: I want to play with *Maven*.

Braddlee: Right. I just want to get this out of the way. For those of you who do not have the handout, this is the URL where you can get the handout. It's not there now. It will be there by this weekend.

Kevin Savetz: And we apologize. There should have been enough handouts for like two for every person that's been here. So either somebody went home real happy...

Braddlee: Or there's more of you than we expected or something.

Kevin Savetz: Yeah.

Braddlee: Let me see if I can get this to wrap. Here we go. Okay.

That should all be in one line. That's the URL where you will find... that's the one we're telling people, right?

Kevin Savetz: That's it. That's what we're telling people.

Braddlee: We're going to try to keep this reasonably updated as new versions come out, so you might just want to make a bookmark and then later on when you want to try *Maven* or *NetPhone* you should be able to find it relatively easily. We're not demonstrating *Maven*.

Kevin Savetz: We've got a connection to Nisernet but I don't hear anything.

Braddlee: Okay. I'd like to try to get this out of the way [if] we can, it's a broken little... All right. We're probably not going to be able to actually demonstrate this product, but you can see that this is the main *Maven* window. There is... you can press the button and you can speak into it and if we were connected somewhere, it would transmit my voice in real time.

Although we can't demonstrate this program, we'll show you *NetPhone* and it's reasonably the same, although like I said, *Maven* really wants a faster connection to work properly. You can turn off and on the other person if you want to temporarily turn off your speaker.

To connect to a place, you hit "add user" and then you type in the address of the site that you want to connect to. And this can either be an individual person for a one on one conversation or it can be a reflector for a group conversation.

Some reflectors are public and when you get there, you're just going to find people chatting up a storm about who knows what. Some are private and some businesses have private reflectors for people actually trying to do serious work.

The upshot of this and *NetPhone* and [*Maven*] is it can work... when the Internet connection is right and assuming that you and the person you're talking to have a fast enough modem, this can work as a viable alternative to picking up the phone and dialing long distance.

But you need to try it once or twice to see... get a feeling for your application and how it's going to work. I've talked to people... I live in northern California, I've talked to people in southern California and it sounded bad and then the very same [day] I connected and I have a perfect, crystal clear conversation with some guy in Australia.

So it works. This is all cutting edge. And it's nifty but not necessarily it will work every time.

M: [Inaudible]

Braddlee: When you're doing Internet audio conferencing and video conferencing, there is always a small delay which is called latency which is basically you speak, the computer encodes it, the modem encodes it, sends it... but it's a very small delay and usually less than 2/10ths of a second.

And sometimes it's not noticeable at all, not unlike the old..., twenty years ago, making a phone call via... over satellite and you say something and then you could like hear your own voice again as it echoes back. That happens sometimes, but not always.

So *Maven* isn't much to see. It's a one window interface.

M: [Inaudible]

Braddlee: To set up a reflector site, basically you need to have a... I believe they all run on UNIX boxes, so you have a UNIX machine and there's a different piece of software called the *CU-SeeMe* reflector which also reflects for *Maven* since it uses the same audio protocol. And you have to download, compile and set up the reflector on your UNIX box and then give that IP address of that machine to the people that you feel...

M: What does the reflector box actually do?

Braddlee: Basically, as I understand it, it listens to the port, the audio port for *Maven*, from one person and distributes it to everyone who is connected. So if five people are connected, you can think of it as a hub... as the reflector as a hub and there's five spokes coming off of it. And if somebody at spoke one says hello, who is out there, the reflector gets it and then retransmits that information to the other four people.

Kevin Savetz: What that means is the individual client doesn't have to do the work of connecting it to all the other clients. And a lot of the processing mode is done on the more heavy duty hardware.

Braddlee: Right.

M: [Inaudible]

Braddlee: Yes. You can just do a direct, one-to-one if there's somebody in particular that you want to.

M: [Inaudible]

Kevin Savetz: Yes. It's all true for *CU-SeeMe* as well. So basically, I mean, the Internet is itself a uni-direct... I mean not a uni-directional, but a one-to-one transport protocol. That's why you have to deal with this whole reflector business because you talk to the reflector and it talks really individually to the other people. And you can't just broadcast on the Internet.

There is an emerging technology called the M-Bone, Multicast Back Bone, and the M-Bone is a virtual network layered on top of the Internet. It's basically Internet-connected machines that are very powerful that have special software that let them broadcast as opposed to unicast, so if you're on the M-Bone which requires a powerful computer and a lot of bandwidth, you can basically say hi, how are you and yourself broadcast to everyone who is listening on that channel or to that port.

But this is cutting edge stuff. Basically if you want to be on the M-Bone, it requires like a Sun or another high-end workstation and a lot of bandwidth. ISDN won't do it. You need at least a T-1 connection to do a viable M-Bone stuff. A lot of fun, but not ready for prime time if you're just a person dialing in from home or someone at a small business who wants to use multimedia applications.

Braddlee: Unless you want to spend \$1,600 a month on your Internet connection.

Kevin Savetz: Right. Yeah. Next I'm going to bring up... any more questions at this point?

This is *NetPhone* which is a commercial application. It's also commercial quality compared to *Maven*. It has a lot more features and is a little bit less prone to crash. It works under less bandwidth.

Okay. It actually hears me. That's good.

NetPhone has the ability to connect to one particular site or you can connect to a net pub which is a specified meeting place. And I think this is... this product by the way is put out by a company called Electric Magic, www.emagic.com for information. It's like \$50, I believe. So we have connected to the net pub at EMagic. And there's currently two other people there. There is me, Kevin Savetz, and I didn't change my preferences so it still thinks I'm at home in Eureka. And then there's Jay in Toronto, Canada and then this gentleman in Iowa.

So we want to talk to Jay. Jay, can you hear me? Oh he hasn't answered yet. It says waiting for answer. So I've called Jay. I saw him, I hit the call button and he has a little... a ringing phone on his screen which he may or may not decide to answer. If he's already on a call with someone else, he may ignore me.

So Jay's not interested so we're going to hang up on Jay.

We'll try Vincent. Waiting for answer. Of course nobody is interested in talking.

Braddlee: Nobody wants their fifteen minutes of fame.

Kevin Savetz: No. No one wants their fifteen minutes of fame. You can have it ring, you can change the ring sound and you can have it not ring if you're already talking, or you can have it be like call waiting, excuse me I've got a call on the other line.

You can use a bunch of different encoding mechanisms. Some are better than others. GSM and GVSD are fairly standard. I think GSM is the one that is cross-compatible with *Maven* so people don't necessarily have to be using *NetPhone*.

The call was ignored. He didn't want to talk to me.

Some products, especially on the PC use proprietary encoding... audio encoding mechanisms. And that means, if you're using for instance *InterNetPhone* on Windows, you can only talk to people who use *InterNetPhone*. And so far, there aren't any applications for the Macintosh which are strictly proprietary. So they're very cross-compatible. Except *PGP Phone* which we'll look at. If you want to use encryption, you need to be talking to *PGP Phone* as well. But we'll look at that in a moment.

Not being one to give up easily, I'll check one other net pub and see if there's anybody there. There's Jay again, but... okay we'll try Jay one more time and if not we'll get on with our life.

This program also gives you the ability, you can select push to talk if you want to... like a walkie talkie you press the button to talk or you can use a squelch mechanism where whenever you speak it notices that you're talking and so you don't have to actually be at the computer or have your hands on the mouse.

We tried to get someone from Electric Magic to demo it but they're all out of town today. Apparently they're at some show. I can't imagine where.

Braddlee: We can come back to that.

Kevin Savetz: We will... I would like to come back to this later and actually try to demonstrate it, but for now these two guys are dull and we'll just get on with our lives.

Would you like to talk about *PGP Phone*?

Braddlee: Sure. This means we're going to have done three things in a row that we aren't actually going to be able to demo.

Some of you may be familiar with PGP, the program for Pretty Good Privacy which is encryption software for e-mail and files. We're going to hopefully take a look at that a little bit later on.

But at this point, we kind of wanted to talk for a couple of minutes about *PGP Phone*. This is a brand new tool. It is very much in Beta. A lot of the features are not yet implemented. But what *PGP Phone* allows you to do is have secure conversations, phone-style conversations either over a conventional phone line or soon over the Internet, with basically military-grade encryption.

Why would you want to do this? You have... perhaps you have proprietary information that you need to be discussing with someone and you're not confident that the phone connection that you're using is secure.

A lot of the reason for *PGP Phone* being available is an alternative to a government promulgated standard called Clipper and Skipjack which are standards for public systems for doing phone conversations.

One of the big differences between *PGP Phone* and the government sponsored standard is that *PGP Phone* does not require the use of key escrow. Key escrow is a system by which you

and the person you're talking to are the only people that can understand and hear your conversation with the potential exception of the government.

In the Clipper Key escrow system, the government keeps a set of keys to your equipment which under a subpoena they can call back and use to listen in on your phone conversations. A lot of folks who are involved in civil liberties issues have a significant concern about this, specifically relating to the potential for abuse.

One of the things that's going on is that as more and more of the stuff we do becomes wireless, things get around, things become wireless and things that were once wireless, like televisions, become on wires.

A lot of our conversations are available to a lot more people than they used to be available to. And it's not so much a case of you necessarily have to have something to hide, it's more that you don't necessarily want to broadcast your business. So this is the first step towards that type of technology.

The Internet side of this is not yet implemented. It is expected to be implemented by the end of the month. The software is available from MIT.

Kevin Savetz: That is... you can connect over modem to someone else to speak.

Braddlee: That's correct.

Kevin Savetz: But you can't speak over the Internet yet.

Braddlee: So the analog side of this is put together. The TCP/IP side is not yet put there.

Kevin Savetz: The button is there but nothing clicks.

Braddlee: That's right. In order to use this, you have to have what is known as a key pair which is your public key which you can give to anybody, and a secret key which is only yours that you control with a pass phrase.

PGP Phone also uses something called the session key which is to come up with a unique that the two phone share for the length of session. That is generated randomly through the use of spoken phrases. And you repeat a couple of words to PGP and it uses those as sort of a random seed as a basis to develop a session key which is unique to that session between you and the person you're talking to, and then is thrown away now and forever more.

The sound quality on this is, from what I'm told, comparable to *NetPhone*, better than *Maven* and it has the additional feature of being able to have secure conversations.

So, again, all of these are really sort of demonstration technologies. They're not necessarily something that you're going to use everyday but each of them has it's own features that kind of make it interesting in and of themselves.

To get *PGP Phone*, you just go to MIT's Web site, look in the network directory, and actually I'll give you another URL to put up there. And you have to answer a number of questions about where you're from and how you plan to use it. And this is only available currently for non-commercial use because of the license and the encryption software. There will be a commercial version available within a year.

I've put together a list of resources on that and I'll give Kevin the URL and he can type it in. It's a list of quite a few things relating to PGP and security encryption. It's <http://www.scs.unr.edu/cs/pgp/resources.html>.

And that will give you all the pointers to PGP to *PGP Phone*, to a lot of other things.

Kevin Savetz: And the URL that I have put up actually you do it via... get this information via E-Mail or via the Web. It's a pack of frequently asked questions list about audio-conferencing software. It does not focus only on the Macintosh. It basically is a big list of products for the Mac, for UNIX and for Windows and also for OS/2 that you can use to do audio conferencing.

This pack is changing pretty often since this is a really new field, but if you want to know the explicit details or you want to know what about Windows, you can check that fact as well.

M: [Inaudible]

Kevin Savetz: Are they all connection oriented? Yes. They're not a connection until they do open and maintain the connections.

M: [Inaudible]

Kevin Savetz: Well I'm sorry. Actually, no that's not true because with *Maven* if you're not speaking, if you're not sending anything and if nobody is listening, you're not maintaining a connection to the reflector. They are connectionless. But *Maven* at least is connectionless. I don't know about *NetPhone*.

M: [Inaudible]

Kevin Savetz: Probably. Because it uses a different Internet port. Internet has a concept of ports that if you're sending e-mail, you are... you may be using port 25, but if you're using Telnet, the UNIX machine or the [inaudible] use port 23 so basically they can tell, the snoop, can tell what you're doing.

M: But the package themselves, are they audio files or are they scrambled?

Kevin Savetz: They're not really audio... since it's a live thing... I mean when I speak, using *PGP Phone*, it's streaming. So it's not like making a Macintosh audio file. Basically I say "hello" and before I'm finished with the word, the beginning of it is being sent to you. So they're individual sound, soundlets packets I guess.

Braddlee: So anybody that's between you and wherever it is that you're headed who wants to intercept those packets has the ability to do so unless they're encrypted.

It's not that anybody in the Internet anywhere can eavesdrop on your conversation or intercept your e-mail but that potential risk does exist and if someone is very interested in doing it, the technology definitely exists.

Kevin Savetz: We're still going to have wait to demonstrate *NetPhone* but we're going to do it if at all possible.

M: [Inaudible]

Kevin Savetz: We tried to do it. That's what we tried to do.

Braddlee: All of our buddies are flakes.

Kevin Savetz: Nothing. I just don't have any friends.

Braddlee: *CU-SeeMe*.

Kevin Savetz: *CU-SeeMe* it is. And that should work out.

Braddlee: Actually that should work pretty well since we have a nice fast connection. I will get out of your way.

Kevin Savetz: I hung up on him. Bad timing. We'll go in one more time. Someone was calling me. Yeah. But I didn't hear the ring until after I had typed quit. It must have been this guy. And I hope... I think that this is... Hello?

[Voice]: Why did you hang up?

Kevin Savetz: Sorry about that. We're demonstrating *NetPhone* at Internet World. So you can say hi to about thirty people if you want to.

[Voice]: Really? Hey, how are you guys doing? I'm sitting at my desk at work catching up on *NetPhone* and it's pretty cool. Anyone there?

Kevin Savetz: Yeah. Sorry about that. I'm trying to adjust the levels on the mic here. So where are you located?

[Voice]: In Burbank.

Kevin Savetz: Burbank, California. All right. So we're actually, despite what the thing says, I'm in Boston, so I think we've got a pretty good connection for being across country.

[Voice]: Yeah, not bad. It ain't costing you anything to use it.

Kevin Savetz: That's right. So anyway, okay, I've demonstrated this and I need to get on with other things, so nice talking with you and have a good day.

[Voice]: Thanks for blowing me off, buddy.

Kevin Savetz: I've played with... I mean, it sounds pretty good I think. And *Maven* sounds almost as good, but I may have totally messed up here. My problem with this is, although it's fun, it's like CB radio or ham radio, you're talking to strangers and you're like okay, what am I going to talk with you about. So in my opinion, if there's someone out there you want to talk with, that's, an associate or a friend already, it's quite useful assuming they have the same similar software.

And if you like chatting with random strangers, you can do that do. I've used it from California to talk with my friend, Dave Taylor, who at the time lived in Indiana. So we saved a couple bucks on phone calls and we only spent half of our time going what, say that again? But it was free damn it, and that's what's important.

M: [Inaudible]

Kevin Savetz: Right. With this program, assuming...

M: So you can't just use an e-mail address to sort of establish that you have the software?

Kevin Savetz: Right. If you want to connect with a particular person, you can type in the IP address or the name of their machine. And you have to know... it's not like an e-mail address. You have to know their certain IP address. And if you want to just talk with a stranger, then you can go to a net pub and it will do the dirty work for you.

There's also a problem, a glitch I guess, with *NetPhone* and all these products, if you are using ISP, an inter service provider that gives you dynamic IP addresses, that is every time you log in you could be... if you have an IP address, then you don't have a set home where your friends can find you. And there are ways around that but it's another piece of software that gives you like a fake IP address, a fake domain name so people can find you.

But anyway, now you've heard it and we talked with some guy in Burbank.

Next up is *CU-SeeMe*.

Braddlee: Yep. *CU-SeeMe* is video... desktop video conferencing software developed by Cornell University. It's being used a lot, particularly in K-12 for things like collaborative education, small groups of students working on things like science projects, research, this type of stuff.

It makes use of something we talked about this morning which is the Connecticut *Quick Cam* which is a \$100 hardware widget that is a [inaudible] device, black and white, 16 gray scale video camera that you can see up on that sign. Kevin has connected to himself. That is Kevin because we can see his name above the frame.

CU-SeeMe also works like *Maven* through the concept of reflectors which means that you can have a remote hub running at this time only on a UNIX host. Did you try a unit?

Kevin Savetz: No, I didn't, no.

Braddlee: If you can get in, that's probably your best bet.

An individual reflector will support up to eight to twelve conferences at the same time. One of the things you can do with *CU-SeeMe* is that by building reflectors on top of each other, you can have sort of the mother reflector, talk to other reflectors and then each of those eight reflectors can talk to either more reflectors or to eight individuals per unit.

You can develop large video conferencing that way. *CU-SeeMe* at that level is much more effective to have a small-scale broadcast tool rather than as an actual conferencing. You don't really want to run a 64 person forum using *CU-SeeMe*.

Kevin Savetz: Not that there would be room on your screen with all those windows.

Braddlee: Right. Exactly. Actually, I think actually the client stuff actually maxes out at 12.

Kevin Savetz: Okay. I usually have luck with Cornell.

Braddlee: Now what we're doing here, we're trying to get into a public reflector. These are pretty popular and you get this a lot. Too many participants. So... and I have a private reflector running down in Las Vegas but it has blown up on me so we can't connect to it.

Kevin Savetz: You can actually change, if you want to you can have it mirrored. Whichever, nearer to you or not nearer.

Keep talking, I'll keep trying.

Braddlee: Yes. One of the things that *CU-SeeMe* does is that... there we go, so this is probably broadcast only. So, tell it to "show all." Yeah. And then turn off.

Kevin Savetz: We're not broadcasting.

Braddlee: What you're going to see here, is you're going to see the current shuttle flight. NASA runs a reflector which is a broadcast reflector. It's not... we're not going to interact with the folks at Mission Control right now, but what they do is they run a live video feed 24 hours a day, 7 days a week.

And [inaudible]... This is great fun because you can really impress your friends that you've been watching the space shuttle on the Internet. Also, quite often they show views of earth from the space shuttle, and it's just really cool. You can see yourself floating by.

If you have cable, they also broadcast this on... like on it'll be like channel 103 or something like that and they never tell you about it, but you get the same thing on the Internet. It's a reflector you can usually get into.

Kevin Savetz: It's a great way to short band within your local area network and really like endear yourself to your system administrators and local network folks.

You'll notice that right now we're running about... I'm below the Mission Control window. This is fairly slow for *CU-SeeMe*. We're only running about one and a half to two frames per second but we're using 43Kbs bandwidth.

Braddlee: Right. So this is using...

Kevin Savetz: Half of a full ISDN link.

Braddlee: Right.

Kevin Savetz: Pretty much. And we're not even sending video which would take even more, so if you have a network administrator that likes to watch current bandwidth usage and you want to make sure that they're awake, go ahead, plug this in, watch the numbers jump and have them come by and go, "what are you doing?" Then you can show them and they'll go either like "wow that's really cool" or "get that thing off my network." One or the other.

Now if we have heard *Maven* before, you would recognize that crystal clear sound quality from *Maven*.

Braddlee: Also, that sound is coming from space.

Kevin Savetz: Yeah. That is true. Oh well. Okay. Yeah, basically *CU-SeeMe* ... *Maven* was done by a guy, Charlie, do you remember his last name?

Braddlee: I don't.

Kevin Savetz: Charlie Pride. No. Done by a guy at the University of Illinois. *CU-SeeMe* used to be a video-only thing and they said hey, you've got an audio product with no video, we've got a video product with no audio, lets put the two of them together.

Braddlee: Okay. If you go into some of the public reflectors, which we will get into, I promise, you will start... if you ever used IRC, Internet Relay Chat, on a regular basis you will notice that certain people are there all the time. These are what we call the addicts. And *CU-SeeMe* has its own few addicts which are just basically the same as the full-time mothers except people with more money and better Internet connections.

Kevin Savetz: Or offices.

Braddlee: Or offices. Or whatever. Some people... I mean, it's fun... if you have the bandwidth to spare you come in in the morning, you log into *CU-SeeMe* and then people can come in all day and see you typing at your machine.

Kevin Savetz: One of the things that *CU-SeeMe* has is if you don't have enough bandwidth to run both the audio and the video, you can do incredibly slow video, like .6 frames per second video and then go ahead and talk down the window.

M: [Inaudible]

Braddlee: If you're doing it just over your internal LAN, for example, my boss works down in Las Vegas, I work in Reno. Usually the days that I'm down in Las Vegas, he's up in Reno. And we tend to miss each other a lot. So we actually use *CU-SeeMe* for real stuff.

We have meetings once a week and generally what we do is we put the speaker on to get the better audio quality over the telephone and then just use the *CU-SeeMe* window as a way to have a chance to see what each other is up to and to be able to have a little more [inaudible].

That I think is pretty much one of the things this is really good for. It's good for small scale video conferencing and linking with somebody on a regular basis.

We have large scale video conferencing [inaudible] compressed video sites straight across the state, but you have to schedule those. We don't have to schedule the use of *CU-SeeMe* and *CU-SeeMe* doesn't cost a hundred dollars an hour. [inaudible]... still working on the compression and they're still working on the [inaudible].

You can see how it's chunky. It starts building the information based on... Stuff that looks the best, frankly, is stuff that's not moving, but the backgrounds, the desk that no one is sitting at looks really nice. And the way the encoding works is that it only updates things that move, so if someone is jerking their head around a lot they're going to appear very chunky and you just might see great globs where their head used to be.

And the faster your connection the better it looks so it looks more at the center of the screen [inaudible] critical information than around the side, but basically the software itself looks more at the center.

So, Doug is there.

Kevin Savetz: Do you know this guy?

Braddlee: So here is this guy and he can [inaudible] the very bottom and there it is.

Now this gentleman is the only guy who is logged in who is currently using videos in *CU-SeeMe*. However, there are five other people who either don't have their cameras turned on or perhaps they're using *Maven* [inaudible]. That voice you hear is some of these non-video people talking to one another.

What's he doing? Oh he's waving. My monitor is up there a little more frequently than hers. She's just like sitting there doing [inaudible].

She sees us. Yeah. We haven't spoken with them but...

And things get... oh, and actually Kelly is looking at me [inaudible] open and she's looking at me.

We can change all sorts of things, whether they can you and you can get data on how much bandwidth you're sucking and how your... how many packets you're losing and that sort of thing.

But basically we are sending at about twenty... at this time between ten and twenty kilobits per second and we're receiving at between about twenty kilobits per second. So we're sucking a good amount of bandwidth.

Braddlee: ... packets which are [inaudible] please deliver me quickly but if you need to drop me on the floor that's okay. And that's why we're losing so many. There are other packets which are high priority, I mean, they can be delivered more slowly but they're more important and they'll be delivered with more accuracy. Does that make sense?

Kevin Savetz: I think that's *CU-SeeMe* in a nutshell.

Braddlee: That's *CU-SeeMe* in a nutshell. And are there any questions? Yes sir?

M: I'm going to have to get a big blackboard or piece of paper that I can...

Braddlee: No they don't. Actually you get some reflector addresses in the package. The commonly available public reflectors, those are the ones we've been banging on. There are a couple of Web sites that deal with *CU-SeeMe* which the most obvious one is *CU-SeeMe*, *SeeMe*, all one string.cornell.edu.

And there's a link to there to a guy at Indiana State. And I can't remember his name off the top on my head. But he has some very good information about *CU-SeeMe* as a Web resource. One of the things that he has is the *CU-SeeMe* reflector list which is a list of a lot of the publicly available reflectors.

The last time I looked for a *CU-SeeMe* reflector list, the only one I found... this was, I don't know, a month and a half ago, the only one I found the guy wanted money for. And that would have been okay but then he wanted me to pay with net cash or something, and I would have sent him a dollar or whatever in the mail but he wanted me to pay with net cash and I didn't want to get into setting up an account and all that garbage. And I didn't want to get into net cash...

What he did was he set that up to encourage people to use E-cash because he wanted his people to start experimenting with the idea of doing financial transactions over the Internet. And he was charging a quarter a pop so it wasn't like he was trying to make money on it, he just wanted people to use the technology. It was something that he had that was in demand and he felt that the quid pro quo would experiment with this.

He promised the e-cash trial ended late last month, and now you have to deposit real money which you didn't have to do before. And e-cash would just give you funny money to play with. I sent him an e-mail and said, hey the e-cash trial is over so the list is now available.

It should have been unlocked. He said he was going to.

Kevin Savetz: Okay. Cool.

Braddlee: So you should be able to get to him.

Kevin Savetz: Now you know, now we know.

M: [Inaudible]

Braddlee: Yeah. Kevin, put it up on the screen.

M: [Inaudible]

Braddlee: There is a Windows version of *CU-SeeMe* which I have not used but apparently it works pretty well, but it will not encode audio. It will play audio however.

Kevin Savetz: And the one that encodes... and one of the limitations was that the CUC, the Connectics Cam for Macs... for Windows wasn't available until middle...

Braddlee: Yeah. It just came out really recently.

Kevin Savetz: Right.

Braddlee: In fact, I'm sure if you try to order it today it will be on back order. I mean it just came out.

Kevin Savetz: Yeah. But it's something that is theoretically possible.

Braddlee: And you also need a video card.

Kevin Savetz: Not with the *Quick Cam*.

Braddlee: Not with the *Quick Cam* ?

Kevin Savetz: Serial port.

Braddlee: Great, good. Okay. That's progress.

Kevin Savetz: Cheap and dirty.

Braddlee: Great. Lets move on. Next question?

M: When someone uses *CU-SeeMe* to do essentially a broadcast [inaudible]?

Braddlee: No, they're still using the reflector technology to... you're hitting one reflector which is basically broadcasting but it's not really, it's saying here's some information, here's some information. It's not really..., it's not like sending it to everybody at once. So it's using the reflector.

The M-Bone technology is going, I believe will be available for the Macintosh in six months or so. Apparently there are... the low level M-Bone tools are being developed. And once those are developed, programs like *CU-SeeMe* will be able to use the capability.

So not available for the Mac at this time unfortunately.

Kevin Savetz: Now is it true that... I remember hearing some contacts though that M-Bone stuff can be piped to *CU-SeeMe* reflectors and then...

Braddlee: Yes. Basically the reflector can listen to the M-Bone broadcast, or multi-cast.

Kevin Savetz: But it's not a full-fledged participant?

Braddlee: Right.

M: [Inaudible]

Braddlee: I don't believe it's the same thing.

M: I just wondered if it's same reflectors.

Braddlee: I don't think so.

Kevin Savetz: No, you can't. They're not inter-operable. What they've done with it, they've done a lot of fiddling to make the *CU-SeeMe* stuff work. They've taken some bits and pieces from other things. I think, is [inaudible] the audio protocol that *Maven* is using?

Braddlee: Yes.

Kevin Savetz: That is a fairly standard UNIX protocol, so that that side of it will interact with a lot of stuff that you'll find kind of coming off the disk and the UNIX boxes. But the video stuff itself, they've had to do a lot of... not proprietary tricks, but they've taken the stuff that was existing and really done a lot to tweak it.

Braddlee: Yes sir?

M: [Inaudible]

Braddlee: I think it was... I think that that was actually a tool that lets, that gives you the talk window. It's called *Talk FM*, and frankly I don't know what the FM stands for. But that's kind of a plug in that gives you that talk window for the chat window to use.

Kevin Savetz: Any more questions? Where do you want to go today?

Braddlee: Well I'm operating. Sorry.

Kevin Savetz: Away from Redland.

Braddlee: Okay.

Kevin Savetz: Do we want to talk about NewsNet or do we want to talk about WAIS? I can try to see if we can find a non broken WAIS surfer.

Braddlee: Lets talk about WAIS.

Kevin Savetz: Okay.

Braddlee: We're going to switch from multimedia for a moment to some other stuff. And WAIS is [inaudible] Information Services. It's basically a database access tool. MacWAIS is a really nice WAIS client. The frustrating part in this is that sometimes the WAIS servers are flaky and difficult to access except for the for pay ones.

A real... probably the best, one of the best examples of a WAIS servers is the Federal Register which is available through `wais.doc`.

Now, what Kevin is doing is that...

Kevin Savetz: Let me just clarify something. WAIS is different from all the other Internet search tools, *Veronica* and *Archie* and *Webcrawler* and all those things because WAIS does full text searches. So basically, if you have a lot of text information, you run it through a WAIS server, which it does the heavy indexing and then you can easily search through that text.

WAIS is very powerful, not very easy to use, although MacWAIS helps move it along. And it never... it's been out for a while and it just hasn't grabbed the attention of people, despite its power. It's not real sexy, and as I said it's a little bit hard to use.

Braddlee: And there are a couple... Dow Jones is using WAIS. There are a number of good commercial WAIS implementations. A lot of them are like \$59 a month which is why I don't have three or four of them loaded.

Kevin Savetz: Right. And there are a lot of free databases via WAIS. We'll look in a minute. We'll look at a poetry database. Also, it's very common for a Newsnet new groups to be indexed in WAIS, so you can go back to the recipe, the `old.vegetarian.dot` recipes archive and basically search through every recipe that's ever been posted in there because somebody put it in WAIS.

So that's what WAIS is.

Braddlee: After your operating a schedule program.

Kevin Savetz: Yeah. Using WAIS is kind of a two step process. What I do... the way I think about this is there is a directory of servers and that's what is currently highlighted up there. So what I do is I go in and when I first select a database, the first database I select is the directory of servers which is essentially the databases of databases.

And then it says tell me about, do we want to try poetry?

Braddlee: All right.

Kevin Savetz: So we want to know about poetry. Then it has... we're hopeful... we're saying hey, are there any poetry databases out there in WAIS? And this server is going to tell us if there are.

Braddlee: Notice we're not saying female poets and first name begins with B.

Kevin Savetz: Right. Really general, are there services out there about poetry. And it has found several. One is something called the poetry index. And some of these are kind of cryptic.

There's something called the ANU Buddha-L.

Braddlee: That's Australian National University. ANU has a whole slew of these things, some of which are indexed news groups, some of which are...

Kevin Savetz: Looks like an indexed mailing list, Buddha-L.

Braddlee: Yeah. Right.

Kevin Savetz: So apparently, it's a mailing list that they talk about poetry.

Braddlee: Buddhist poetry.

Kevin Savetz: Yeah. Buddhist poetry.

Braddlee: And you can why don't you just select poetry index and bring up the viewer.

Kevin Savetz: Okay.

Braddlee: So we're going to take the poetry index which has a score of a thousand and so it really thinks that this is on topic. We're going to hit view and it's going to give us some information about.

This is an index of all the poems and reviews published since Volume 151, October 1987 in *Poetry Magazine* of Chicago.

So what we have here is a big index of poetry and we save this link, basically this is a... we save this bookmark, which I already had one, but hey, we just updated it. And now that we've found the index that we want to search, we're going to search that index.

Kevin Savetz: Right.

Braddlee: So this is part 2 and if I can remember how to do this.

Kevin Savetz: Back to sources.

Braddlee: Sorry?

Kevin Savetz: Back to sources.

Braddlee: Back to sources.

Kevin Savetz: And then edit or select.

Braddlee: Okay.

Kevin Savetz: Sorry. Select.

Braddlee: Sources, select and now we want to... we're not going to search the directory of servers anymore but we are going to search the poetry index.

Kevin Savetz: Do you want to talk about Frank O'Hara.

Braddlee: Sure. Frank O'Hara would be fine. So now we're going to tell me about Frank O'Hara and we're going to say ask. It's going to... now it's in a searching directory of servers it's going to search the poetry index. Initializing connection, thinking about it for a while and look at that. It has several hits.

Now you notice over here there's the score. This means a score of a thousand. So according to WAIS this is really, really about what we asked about. A score of 358 is much less... it talks about Frank O'Hara but not so much and a score of 178 down below which might mention him in passing but probably isn't what we want.

Kevin Savetz: And what are the possibilities for those low scores too is it's talking about somebody named Frank but not necessarily Frank O'Hara.

Braddlee: So I clicked on view and apparently it's giving us an abstract.

Kevin Savetz: A citation, yeah.

Braddlee: A citation of the information that's there. And can we get the actual information?

Kevin Savetz: No. That's going to be the fullest... that's going to be the full. What you've got is you've got the index.

Braddlee: We have an index.

Kevin Savetz: Right.

Braddlee: Okay. So now the thing is... so that's an example of how you would retrieve one piece of information. If you were going to use this for the Federal Register, the way the Federal Register works is if you were at a public library, you can get an IP, so you can get them to turn on your specific IP address. Or you can do for free or you can do it as a subscription to the Federal Register for a fee.

You can get access to and be able to search using the WAIS indexing. Everything that comes out in the Federal Register the days that it's published.

So if that's something that is of interest to you to be keeping up with announcements and bids on bids on government contracts, changes in regulations, new types of information that's coming out from the government.

This is a real nice tool to do that with. It's something that I use with librarians at Paramount.

Kevin Savetz: The database that we were just searching was only an index to stuff in the magazine. And I would like to make it clear that there is more tangible, useful information in the right databases.

I did this search once before and we were just searching the wrong place, but I'm going to try to duplicate this now, I went to poetry, one of these poetry indexes. Actually there's real poetry in there, so I went into there. I typed e. e. cummings and actually got some cummings poetry. So that's something that can be useful.

M: [Inaudible] and it seems like all of a sudden, and the Web becomes sort of a glamour application of the Internet, have you seen or is there any way to determine this, a decline in the

kind of... type of information that are being put into like WAIS servers instead of people putting all their effort and energy into Web servers?

Kevin Savetz: I've been thinking about that a lot. I think one of the things that I would say is that there is more free information coming out, but what's happening is because of the growth of the Internet as a whole, there is a huge... a vastly greater amount of pay information or things that are hybrids.

For example, when I think of that, I think of something like CARL, the Colorado Association of Research Libraries where they have... you can go in... you can for free search the on-line index. They index 17,000 journals. And you can get back citation information and limited abstract information on any of those journals for free.

However, what they really want you to do is to request fax copies of the articles, which they'll charge you anywhere between \$8 and \$30. Now if you need that information in a hurry, that's a very useful service.

Braddlee: You picked a really interesting poet here. I'm actually reading some of his stuff.

Kevin Savetz: Yeah. I picked a different database called poetry.source which isn't just an index, it actually has some information and I found some poetry by Frank O'Hara and I also found a biography of him. So this is full text information, not just abstract. So I actually got... did something... we learned about Frank O'Hara.

I didn't mean to interrupt you.

Braddlee: That's okay. That's fine.

Kevin Savetz: So there is free information coming out of the Universities and individuals and all these people have traditionally put free information up on the Internet are doing it, but a lot of other people are doing it and charging for it as well.

I think we're going to see a lot more of that. And I have mixed feelings about that. I think it's good and useful that we're getting that information out there.

M: The people that are putting that information out, are they putting it... the people that are charging for it are putting it... are they tending to put it up on Web sites or are they tending to put it up on a WAIS servers?

Kevin Savetz: Well see, it's not necessarily initially exclusive.

Braddlee: You can access [it anyway] via the Web.

Kevin Savetz: Right.

Braddlee: And so, in some... a few cases, people are putting stuff up via WAIS servers, but you can access them through your Web client and maybe not notice that you're using WAIS.

Kevin Savetz: Right.

Braddlee: It just seems to be an elegant search tool that you're using. And you can avoid this kind of clunky interface.

Kevin Savetz: And whereas you have..., rather than having SQL, all databases will be an extra WAIS server or something.

Braddlee: So I think that the short answer to your question is, people are in general leaning towards the Web but you're going to be able to do things through your Web browser that you might not even have to know that you're using WAIS, even if you are, or other even better search tools.

Kevin Savetz: And you can have WAIS URLs. So that's I mean the browsers will speak, these multiple protocols... WAIS is one of those protocols.

Braddlee: Are there other questions? I read some stuff by e. e. cummings too.

M: [Inaudible]

Kevin Savetz: No, this is free. This is one of the random databases that are out there. This one is called poetry.scr.

M: [Inaudible]

Braddlee: Shareware I think.

Kevin Savetz: Actually [it] just went to be free. That version still thinks it's shareware but when I sent them the money for it, they sent me back a note saying thanks for sending us the money but we're going to return your check because it's going to be free in a couple of months anyway.

Braddlee: So that's a misunderstood but useful tool.

Kevin Savetz: Keep going. Keep cool.

Braddlee: Lets see. A couple of other useful tools while we're just kind of playing catch all, there is a useful program called *MacTCP Watcher*. If you've ever had an Internet connection that didn't quite work, you're just trying to get it set up and you're not sure what's wrong, *MacTCP Watcher* is a freeware I believe... yeah, it's free for non-commercial product that lets you diagnose Internet problems.

It's not real sexy but, you know, it does the job. For instance, if you need to PING something, say "well, do I have Internet kind of activity, can I reach other computers that are out there?" It will send out PING packets and say you there and say hey you there every few times a second. You can see if your Internet connection is reliable. In connecting to this computer, I can get there 80% of the time.

Kevin Savetz: Well, we're fast but we're not reliable.

Braddlee: We're fast but we're not reliable. Right.

Kevin Savetz: Yeah. 20% is pretty unacceptable.

Braddlee: I happen to know that... so we know that... all right, we have a connection but things aren't perfect. That computer is usually pretty slow anyway. And that can be the problem or a connection might be noisy or something like that.

Kevin Savetz: See, just to give you an idea, last... you can see that we're talking about, like, 16/100ths of a second, 15/100ths of a second.

Braddlee: To get to California.

Kevin Savetz: Right.

Braddlee: Last night, in my hotel room through my commercial Internet provider on the 28 PPP connection, it was taking me an average of 1.54 seconds to get a packet turned around between here and the West Coast which is not acceptable.

So it's a real basic level tool itself. Are you getting through, hello are you there, which is more reliable as a basis for complaining about a connection than "my Netscape won't work." Because you can come back to the provider and give them real information, and say, I'm losing 35% of my packets and it's taking a second and half for turnaround time and you need to do better than this.

Kevin Savetz: There's another diagnostic kind of tool called *MacTCP Monitor* which deserves about two minutes of our time which lets you know when you're using other applications... I'm going to bring up a Web page here.

It lets you know how fast you're actually moving information. And it basically gives you a bar graph with all these pretty little bytes that tell you how many... I think this is bytes per second you are currently moving right now. So as we download this Web page, 8,652 bytes per second is our maximum which is pretty darned fast.

Braddlee: Lets bring *CU-SeeMe* back up for a second.

Kevin Savetz: You want to? All right.

Braddlee: I'm going to ask you this live because I haven't asked you before. Do you know anything that does trace routes?

Kevin Savetz: There is a program called *MacTrace Route*. It only works over the Internet connections.

Braddlee: Okay.

Kevin Savetz: It doesn't work over modems. Do you understand what trace route is?

Braddlee: Sure.

Kevin Savetz: Trace route is something that will go along with PING and DNS Check and the other things that are in *MacTCP Watcher* in that what will happen is, frequently if you have a broken Internet connection, you kind of want to know what link failed.

Trace route traces the route your packets are taking from your Internet-connected computer to the destination you're trying to reach and provides you back with information such as how long it took to make each of those hops.

And really, if I understand it correctly, really what it is is successive turns but it takes each of those steps along the way and comes back with the information.

So that's another useful thing to have in your toolkit if you are trying to find out why you can't get to a particular Web site. And it gives you the kind of information that you can then feed back to your network administrator and your net service provider about why something isn't working. And this may not be something you may use everyday, but when you need them they're really helpful to have.

[Inaudible]

Braddlee: Oh it's not UDP. It doesn't look UDP. So anyway, we can't see exactly how much bandwidth we're sucking, but too bad. So those are two useful diagnostic tools. I'm trying to think if there's anything else that you just need to have.

Kevin Savetz: And those are... how about Switcher?

Braddlee: *MacTCP Switcher*... for instance, you have a PowerBook and you use it on the road and you use a modem to dial into the Internet but you also have an Ethernet connection in your office, those probably require different setups in *MacTCP*., you have a different server information or you have to dial in with *MacPPP* with one but not the other.

MacTCP Switcher is a simple program that lets you save two or any number of common configurations. So when you're on the road you can very easily switch your settings to one way and when you get back home you can switch them to another way.

It's a little shareware program and it works. It's a one trick pony but works well for what it does. And if you travel a lot or if you're on two different networks somehow it can be useful. There is a point or two I believe in the handout as well.

Several people are asking about servers and so I would like to get you going on that.

Kevin Savetz: Okay.

Braddlee: Since this is your thing. FTP servers and all that good stuff.

Kevin Savetz: Sure. Okay. There are a couple of things about servers. Obviously what we've been looking at up to this point has pretty much been software for allowing your Mac to bring other things in off the Net.

Another thing that you can use your Macs for is to provide information. There are a couple of these. The first one, and to be honest this is a brand new version that I haven't even really looked at. It's called *FTPD*. It's by Peter Lewis. And you've got two components of it.

The first side is *FTPD Setup*. What this is asking about, this is saying... this is an *FTPD* and most of the Peter Lewis applications, in addition to using *Internet Config* which we talked about some this morning, also take advantage of *Civic* which allows you to... allows the provider of the software to let you know when it has been updated.

And so what this screen is doing is saying if you want to allow *Civic* and you want me to let you know when I have a new version of this out, go ahead and say yes. If you don't want me to know that I'm using this program, then just disable it. And since we don't really have anything to hide, we're going to say allow.

The FTPD startup screen is \$10. Say thank you. And go to the main screen. This is kind of interesting. This is something that changed in the last... recent version. FTPD used to only do FTP serving, the File Transfer Protocol. We looked at *Fetch* this morning and *Anarchie* this morning as ways to get files off the Internet. This allows you to serve them.

On any of these server software that we're going to talk about, I would pay very close attention to how you're setting it up. If you're not familiar with users and groups and some of the basic ideas about how to do security on a Macintosh, you're probably better off leaving these things alone because you have the potential to set things up in a fairly unsecure fashions.

We'll take a look first at the FTP setup. So for example here, I'm going to set this up just the way that I have mine set up on my Mac back in my desktop which is that I don't give users and guests any privileges. I don't let anyone other than myself log into this. But I give myself full privileges so basically I can upload, I can download, I can delete and I can move things using FTP.

Braddlee: So if you forgot to bring something to Internet World, you can right now log into your home machine?

Kevin Savetz: Exactly. I can log into the machine on my desk and as long as it hasn't crashed since the last time I've left... for example, our site doesn't support ARA. I can't use that for remote access through our modem pool which is something that I find kind of frustrating but the Novell people can't use Novell either, so I guess we're kind of on even ground there.

But we do do TCP/IP in the modem pool, so I can set the FTPD server up on my Mac and the file that I've invariably left behind I can then get in and get access to.

Down here we have some control about maximum of users. I think 999 is a little excessive. I hope... really hope that you're not going to try to run a thousand FTP, simultaneous FTP connections off of a Mac. They actually do much better at this than a lot of the people think they do, but I don't think that you'd want to run that.

So all I've done here is just turn myself on as a user, so I'm going to say save for this.

Braddlee: But if you want to run in the anonymous FTP site, you can certainly do that by allowing guests.

Kevin Savetz: That's right. For FTP users, basically what this is is this tells you to set up a particular directory so if you do want to give users other than yourself access to the site, or you want to, in the interest of having better security, have even your own access limited to a couple of files or a couple of folders, this allows you to set this up, to set up a folder as your particular log in directory. Probably pub would be a good name to start since that's the convention from the UNIX FTP.

Go ahead and save that.

M: [Inaudible]

Kevin Savetz: That's right. It only allows from there down so in other words, if you have a pub directory, only things that are in that pub folder and folders inside that folder people will be able to [be] looked at. They have no access to anything else. None of your WordPerfect files, none of your Lotus spreadsheets, none of your Excel stuff. Nothing else, just things that are in there.

There are a couple cute things here that you can do here about speaking messages and play sounds so that when it tells you it's woken up and someone is trying to log into your computer, it gives you an alert on that.

User restrictions: gets, puts, whether or not they can upload stuff, whether they can download stuff, allowing them to change their individual passwords, allow them to do Apple script searching I believe, allow them to delete or rename things.

You can allow people some fairly serious stuff here if you're not careful about how to set this up.

Sorry. We've just been there.

Okay. Now, one of the neat things about this is that it will also be a *Gopher* server and you can give it a name as a *Gopher* host and tell it the root directory in the same way that you gave it a root FTP directory. Set it as to whether the *Gopher* course is [the] standard port 70 or someplace else. And then you would turn the *Gopher* on here.

Okay. So if you want people... *Gopher* clients to be able to access your Mac and provide *Gopher* information, this is a \$10 tool that will let you do this. And not only that, but it is also a limited Web surfer.

So if you've got... I wouldn't try to run the *QuickTime* www.quicktime.apple.com off of this but if you've got a couple of pages that you want to serve internally, or you've got a small site that you want to put up and advertise but you don't expect it to have a huge amount of traffic, this is the way to do this.

Braddlee: You don't have a real Web server. There are dedicated server tools for doing that. That's right. Do we have HTTP on your drive?

Kevin Savetz: I don't think so.

Braddlee: Okay.

Kevin Savetz: It's not much to see though.

Braddlee: That's right.

Kevin Savetz: No. And we'll talk about it though. So then we've got the summary. This is basically everything that's going on. FTP is not running. File sharing is enabled. User can log in. Guests do not log in. That's how we set that up in FTP.

I have full access. Nobody else can get in. We didn't turn on *Gopher*. We didn't turn on Web.

Now you have to have file sharing on in order to do this because if you don't have file sharing on, you can't serve anything because that's a necessary and sufficient condition.

Braddlee: We have just set up a working FTP server basically in the time that you were watching this.

Kevin Savetz: Right.

Braddlee: I have done it for UNIX. It took days.

Kevin Savetz: Oh yeah.

Braddlee: In UNIX, everyone... a lot of people that use UNIX, UNIX is a great operating system but if you're interested in just doing something and you want it to work well and work quickly, Macintosh is a fine way to do that because... I mean honestly, I've done it on FTP and

there's lots and lots of security issues, compiling your FTP server when the one that came with it didn't work quite properly.

So basically what we did in five minutes can take a lot longer on UNIX.

M: [Inaudible]

Kevin Savetz: It depends on what you're trying to accomplish. For example, I would have no problem about running all these things off the Quadra 610 that sits on my desk.

Braddlee: Yeah.

Kevin Savetz: As long as it has a decent amount of memory and a fast Net connection just like you would have for a UNIX machine.

Braddlee: Right. Because it sits on the Ethernet connection in the computing center about fifty feet from our Hub Router. Also, I'm not trying to use it for heavy-duty stuff. And this is actually connected to my FT... this is my Mac back in Reno using FTPD and basically there's a welcome message that's like, that's Gertrude, that's the Mac's name and it's saying how is it going out there in the world. How come I never get to go anywhere like Howie does? This is Howie over here.

Okay? It says if I'm logged in, and directory's route and from here basically I can see my whole hard drive. Okay? And you can see exactly how tidy or untidy I keep everything.

You know, and I can go in here, I can go to PowerPoint. And I can come back in and I can retrieve my PowerPoints, my PowerPoint demo. So if I've gone out and I've found out that the version that I have is the wrong version or whatever, bingo, zap, we grabbed it.

And it keeps logging. It does a nice job of that basically. What I've done, too is, the other part of this that we should really show you, is what I had showed you before with the set up information was one program called FTPD Set Up. The program that actually does the serving is this guy here, FTPD, the FTP Demon.

And I've stuck him in my start up folder and the systems folder and so that every time that the Mac boots up, that's automatically fired off. Okay?

And I keep a couple of these things. I keep FTPD in there. I also keep a Finger Demon that responds to Finger requests. I also keep a Talk Demon that responds to Talk Internet chat requests.

And so those automatically just start up. And the FTPD keeps nice logging. It keeps it for as long as you want. It tells you who logged in and how long they were on for, what they took, what they put up. You know, pretty much everything that you would want.

And it's a high security, low cost...

Kevin Savetz: It's very high security and the reason is, unlike if you have a UNIX system which is really the thing to compare it to because that's where traditionally all of this stuff has been done, if you set up a UNIX machine to be an FTP Demon, the UNIX machine probably by default also knows how to do Telnet and do Mail and everyone of those layers has potential security problems.

And there is a few old ways to hack into a UNIX machine, get route access, get super user access to the system using only e-mail.

With the Macintosh it's simply not possible. If you only want to serve FTP, it's the only thing you have running, there's no way anybody can send you e-mail or can [TelNet] into the system.

So it's a very, very secure way to go. And it's even more secure if your Macintosh is not on... isn't connected with... you don't have all of your business's private information on that Macintosh; you keep that elsewhere on the network and it's even more secure.

Braddlee: Yeah. I had an interesting conversation. It's one of the things I'm looking at right now where I'm working is, we want to do some fairly serious Web serving and the question is do we get a Netra and get Netscape which, even though the Netscape software is free for us, there's still the question of using it and administering it. Or do we get a Mac Internet server and do we use Web Star which is the commercial version of Mac HTTP, the free Internet Web server.

Even though I'm fairly Mac biased, I try to keep an open mind about things and really, at the end of talking to the Apple folks and talking to the Web Star folks and talking to a couple other folks about things like CGI Bin and databases and add ons and the stuff that's going to be available both now and over the next six months, I don't really feel like... particularly when I look at the cost of administering the server in terms of my time, in terms of network administrator time, in terms of difficulty for use both for the users, many of whom are Mac people and who want to do Web development but just really don't want to learn UNIX stuff.

I think it's going to be the performance actually at the low end is higher. You can get a \$3,000 Mac Internet server and the performance is close to a \$7,000 to \$11,000 low end Netra UNIX server.

Kevin Savetz: And a lot easier to set up.

Braddlee: A lot easier to set up. There are some fairly basic tricks that you can play about spreading the load over multiple servers. Right now a Mac can handle a total of 48, I think it is, simultaneous connects... simultaneous in-bound connections as a Web server.

Kevin Savetz: Which is a lot because you're only connected for what, two seconds or something, for most...

Braddlee: Well, actually what it means is actually opening that port. And 48 people all at the same nanosecond saying gimme. And what you can do is through DNS, you can assign your home page or top level page across multiple servers.

If you're getting a hundred hits... a hundred simultaneous hits, you've got a pretty significant project going, but what you can do is in DNS you can randomly assign that initial hit across the servers so you spread the load that way.

Also, by spreading the load across your site in terms of where individual pages lead, which server they go to or for example which server is going to run mail list stuff or database stuff in addition to serving up Web pages.

You can have something which is distributed and really quite comfortable to work with. And I frankly don't see a whole lot of reason unless you're doing something huge to really do UNIX unless UNIX is something that you do already and that you love and that you want to use.

Some of the... there are some flexibilities that you have in UNIX that you're not going to have quite yet in the Mac stuff, but the gap is closing real fast and again, one of the things that helped really kind of resolve things for me was, take a look at the Apple *QuickTime* Web site. That site takes a million hits a day and it is serving up not little text pages but it's serving up *QuickTime* videos, one, two, three meg files. And what they're doing is they're serving all of those hits on eight Internets or on eight Apple Internet servers.

So in other words, for about an \$80,000 investment in hardware and software, they're serving one of the biggest sites in the Net and have very low system administration costs and a very high level of security.

M: [Inaudible]

Braddlee: Yeah. There is Mac DNS.

Kevin Savetz: Mac DNS. That just came out of Beta.

Braddlee: Yeah.

Kevin Savetz: So it's a commercial product and it works.

M: [Inaudible]

Braddlee: It's a commercial product.

Kevin Savetz: It's a commercial product. It's not on our list.

Braddlee: Yeah.

Kevin Savetz: You can get it from Apple I believe.

Braddlee: Right. And I think I may, if I root around I might be able to find some contact information or give me your information and I'll figure out how to get it to you.

Kevin Savetz: I think we beat it up to death.

Braddlee: Yeah. And about five people have left, so I have a feeling that maybe it's the time, but maybe servers aren't...

Kevin Savetz: Right.

Braddlee: I don't know, but that was the FTP Demon. There is a product, if you want to do mailing lists, there's a commercial product called List Star. It's from Star Nine.

Kevin Savetz: Which is the same people that do Web Star.

Braddlee: It's the same people who do Web Star. And I have not used it. I understand it's a very powerful mailing list software so if you want to have huge distribution lists you can do that with the Macintosh as well.

Kevin Savetz: Yeah.

Braddlee: For Web serving, we were... there's nothing to see. It's really dull to look at. There is Mac Web which is the freeware Web server for Macintosh. And then there is a more robust commercial one called Web Star which is from Star Nine.

Kevin Savetz: Mac HTTP.

Braddlee: Mac HTTP, I'm sorry. Not Mac Web. Yeah, and basically the Mac Web and Web Star are the same interface. They're the same software as far as the interface. It's just the code has been rewritten by the Star Nine people.

It runs about four times faster than the free version., that has been part of the primary consideration, the primary criticism of the Mac Web server software was that it wasn't as fast and they've addressed a lot of that concern.

It's three o'clock, do we want to take a five minute break?

Kevin Savetz: Yeah. Why don't we... let's take a five minute break and then reconnoiter and touch on some final things. We'll talk briefly about Newsnet and Newsreaders, although we cannot demonstrate any of them.

And then we'll just open the floor to whatever questions and finish up.

Braddlee: So a five minute break.

[Break]

Braddlee: One thing too, is that we're kind of basing what we're talking about on our assumptions of what you guys are going to be interested in. And if we're completely off-base feel free to say hey what about this, what about that.

M: [Inaudible]

Braddlee: Okay. Well we were going to talk about Java and that will go fast. I suppose if you've been awake during the show you've heard at least something about Java which is a tool, actually it's a programming language that will let you... will make the Web even cooler because you can download little applets, little programs that do things., put dancing bears on the screen or the Energizer bunny or things can happen, play sounds, and nobody's really sure what Java is going to be able to do yet but everyone seems to think it's a nice idea.

There are currently no... do you like my extension? Yeah, I've got one or two. There are currently no Java clients, such as HotJava on the Macintosh. Coming real soon now, likely within a month, you're going to see some Betas that are going to probably, maybe possibly work.

Kevin Savetz: Do cute dumb things.

Braddlee: Do cute dumb things. They exist for Windows and so they should probably come out for Mac relatively soon.

We're doing the microphone dance over here.

Kevin Savetz: There we go.

Braddlee: So in answer [to] what Java is, there's no Java client and therefore there is no Java editor for Macintosh either.

I know nothing about the language and frankly, I don't know what [a] Java editor would look like. As for other authoring tools, if you want a commercial HTML authoring tool, there is one that just came out with a new version 2.0 and it is called... it is by Softquad...

Kevin Savetz: Right.

Braddlee: And it's called...

Kevin Savetz: I'm blocking as well.

Braddlee: It's by Softquad and it's a... I guess a fairly nice HTML editor. Frankly, I'm a purist, I use *Teach Text* to edit all my HTML. And you should too because if you do that, I promise you, you will know HTML. And when you are forced to edit your Web page on the fly, you don't have the editor, you'll know how to.

And editors are kind of nice but they're not a necessity. There are a lot of, I guess you could just say, there are a lot of shareware and free HTML editors. I have tried them all and they are all garbage. And that's why I use just *Teach Text* for Microsoft Word because this one can't do Netscape style lists and this one can't do... doesn't know how to center, and this other one just crashes every third time I use it.

And I have no patience for that sort of garbage so I do it all by hand because it's all up here.

We talked earlier how Netscape has been very aggressive about advancing HTML codes and how the other browsers have kind of lagged behind it. Well, the HTML editors suffer from the same problem.

Kevin Savetz: Right.

Braddlee: If there's something really cool that you want to do that you're seeing being done with Netscape and prototype HTML 3.0 stuff, you're going to have to write it yourself anyway.

Kevin Savetz: Yeah.

M: [Inaudible]

Braddlee: Yeah, and it's kind of nice because you can see it larger., sometimes it bumps up the size. It's kind of fun. If you find it useful, great but...

Kevin Savetz: Or a good *Gopher* can get the HTML extensions for edit.

Braddlee: Yeah, and you can get extensions for Microsoft Word, *BBEdit* and I just started to help you do HTML as well. Yes sir?

M: They just came up with Navisoft?

Braddlee: Navisoft?

Kevin Savetz: Navisoft. Yeah that's the one that we were... that's the one that we couldn't remember the name of.

Braddlee: No, actually I think that Softquad is the company and the one we were talking about.

Kevin Savetz: Oh okay. I'm sorry.

Braddlee: Navisoft is a different company. Do you know what it's called?

M: [Inaudible]

Braddlee: Okay. Navisoft is available on America Online for free.

M: [Inaudible]

Braddlee: So as far as authoring tools it's HTML and nothing else. You can't do Java, you can't do VRML at this time either. Again, like Java and VRML, real soon now, but not quite.

M: [Inaudible]

Braddlee: No. And I believe you'll see those really soon, like maybe within the next couple of weeks.

Kevin Savetz: Like I'm surprised we didn't see any here.

Braddlee: Yeah. I was really kind of expecting to see some Betas on the show floor. I used VRML on Windows for the first time a couple of weeks ago and it was kind of cool. And actually there were, like, five different VRML clients out for Windows. So it's prime-time for there to be at least one on Macintosh.

M: [Inaudible]

Kevin Savetz: I was using a Pentium 75, so not the fastest machine out there, and it was smooth. It was wire frame, but it was smooth. I didn't feel slow and clunky at all. It was kind of nice.

M: [Inaudible]

Kevin Savetz: Well when you're... at least the way it is on Windows, you... it's like a Web page where it will sort... you download the information and then your computer is kind of in control of it so basically if it's a short VRML script, you've got to load a 10 or 15K script and then you can cruise around it all you want. It's not using your Internet connection.

If you're downloading a very detailed area... I downloaded one which was like 200K, you're downloading a 200K file and then your Internet connection is done and then you navigate around it.

So, once it's there, even off line you can cruise around that script and look at your information. Also, in my opinion, it was fun. It wasn't useful though, it was just like...

Braddlee: It's kind of like *Gopher VR*.

Kevin Savetz: It's like *Gopher VR*, I guess, there's another... there is something called Walk Through or Walk Around or something on the Macintosh, I don't remember. Basically you've got a scene and you can walk through it and you can see some pretty pictures but... so it's fun but it's not useful. It's not like you can go into one area and it will bring up a different Web page or something.

It's just kind of like walking through a still picture. And they were... and it was kind of clunky and VR Mail is also evolving standards. I'm sure that will get better too, but the graphics weren't really elegant.

Okay. Any more questions at this point?

Somebody had asked about... talking about Webs, about FTP or Web servers, about what you needed actually as far as an Internet connection goes, as far as Internet connection and what kind of Macintosh. Does anybody care? Or was it just the one guy?

Okay. Well, enough of you care that I'll talk briefly about it.

The gentleman wanted to know if his 28.8 connection was enough to set up a Web server, an FTP server. Basically, for personal use, I think you can get away with 28.8, but if you want any real usage probably not. And I'll explain why.

28.8 modems are relatively cheap and modem Internet service is cheap, but if you make a shareware program and you put it up and make it available via FTP on your Macintosh connected to your ISP 28.8 line, one person logs in to get your shareware program. He has... he or she has full, if you use this term suckage, he has full suckage at 28.8. And he has the full attention of your modem.

If two simultaneous users come to try to come in, they have 14.4 each available to them. Not so bad. If four people come in, they each have about 7,000 bits per second available to them. Now this is only four people coming to one FTP site, and that is completely not acceptable speed unless you have the patience of a Saint.

Braddlee: Or you're a Mac commercial unit provider.

Kevin Savetz: Or right... you're certain Internet providers that are not so reputable.

But for personal use or it it's just you and your buddy getting files... like Braddlee can go in and get his *PowerPoint* documents, that's doable, but if you want anything, to do any real work then you're going to have to get a faster connection.

For most of us, in most areas, and this is not true across the board, it depends on where you are, the next... the cheapest way to go for faster connections is ISDN, Integrated Services Digital Network. And that's a way that you can get a connection at 56 kilobits per second or 128 kilobits per second through the Internet.

ISDN costs more on a couple of the levels. First of all, it doesn't work with a normal modem, an analog modem. You need a digital device called an ISDN router. Depending on how you set things up, you may need some Internet on your computer as well.

On the second level, you need an Internet service provider that accepts ISDN connections. They probably charge more for ISDN connections than normal analog modem connections.

Nominal costs for setting up ISDN, as far as the hardware goes, \$700 for a Nubus card that you slap inside your Mac, plug your ISDN digital phone line into it, and set up some software and you're on your way.

If you want to do it right, it will cost you... I mean that's not wrong, but if you want to do it better, it will cost you more. If you have a small office or a home office as I do, I have a home office. I have three computers and I wanted them all to be on ISDN, so I have an ISDN router from Ascend which is not a Nubus card. It looks like kind of a modem. It's an external box. The sucker cost \$1,400. And I had to buy Ethernet cards for my Mac and also for my Pentium, my lovely little PowerBook already has Ethernet, so I have Ethernet between my machines. They're all connected by Ethernet to the ISDN router.

Braddlee: Do you want to explain, maybe for just a second, what the advantages of stuff like the Ascend router are over like getting like a small [inaudible] or like the configuration stuff?

Kevin Savetz: Frankly, I did it because I heard good things about Ascend and if you have insight into that...

Braddlee: No, I... since you actually set one up because basically it's my understanding that one of the advantages of the Ascend router is that it's much more... configuring routers and setting up and configuring routers presents a lot of technical and security issues.

Kevin Savetz: Setting up a router, no matter what brand you get, is a lot more difficult than plugging in a modem and typing in ATDT. You have to set a lot of the stuff like in MacTCP, only a little bit more complicated.

Braddlee: Of course.

Kevin Savetz: I like the Ascend router very much but there are routers by... I've seen routers by Cisco and Livingston and I am not an expert in ISDN, I'm just a user. So in my particular situation, I have this router which I have set up and when I sit down at any of my three machines and I run Netscape or try to check my e-mail, it rings up the ISDN connection very quickly. It comes up within three seconds. I have my connection, and I start cruising the Internet.

When I don't use my connection for a period of time... a specified period of time, it quietly shuts down. It feels to me like I have a full-time Internet connection. I can sit down at any of my three machines, punch up Netscape, pull the URL and I'm up and it's really fast. It's almost as fast as what we're seeing up here. So that's very nice.

If I had three arms, I could be at all three machines at once and they would be sharing that, which is really nice. But that's expensive and the total cost for my set up was about \$2,000. My ISP for a full-time ISDN with unlimited use charges \$150 or \$200 a month, so that's pretty expensive compared to \$20 for twenty hours for a normal analog connection.

And finally, your phone company charges more for ISDN than for an analog line. If you have normal analog service, you pay X dollars a month and you can talk for as long as you want at a local call. With PacBell over in California, they charge measured rate for ISDN which is a penny a minute which isn't expensive, but it adds up if you're going to be logged in a whole lot.

Other phone companies do it differently. And some have measured rates which are more than others. And some, I believe, have unlimited use but I believe that's kind of rare. ISDN is not available in all areas. But if it is, it's quite nifty.

So ISDN, back to the server thing, ISDN can handle several people at once. ISDN can probably handle ten people at full suckage downloading information which is good for a small server. If you want more than that, then you might have to go to 384K frame relay which gets really expensive and uses completely different hardware. Or if you are really big you can get a T-1 which is really, really expensive but very, very fast.

There's a question back here?

M: [Inaudible]

Kevin Savetz: If you want your own domain name? Basically if you want to have... if you want to be Braddlee.com or in Savetz.org or something like that, what do you have to do?

The organization that administers domain is called the InterNIC, <http://www.internic.net> and they're in charge of all domain names. They now charge a fee for domain names. It's \$100 for the first two years and \$50 for each additional year. It used to be free. But there's overhead in setting these things up.

So, for instance, I am savetz.com. I don't actually use it, but I have it. And you need basically to have, if you have your own domain name, it needs... there needs to be a domain server out there somewhere, a computer that knows, okay, Savetz.com well that's really 199.4.102.10.

Generally, if you have an ISDN connection for instance, your ISP will, for a fee, be your domain name user. Somebody has to be and if you're lucky you can maybe find someone who will do it for you for free. If you're not lucky, someone will charge you for it which shouldn't be more than twenty bucks a month. I mean, that's maximum.

Braddlee: Yeah.

Kevin Savetz: Most ISPs I know of charge a \$50 set up fee for domain service and maybe \$5 a year for maintenance. So you need someone to be your domain name server, and other than that, there's no big mystery to it except filling out the forms and doing it three times because the Internet will keep sending it back because you keep doing it wrong.

Yes?

M: [Inaudible]. Do you get through the e-mail software or do you have to go back to your ISP?

Kevin Savetz: Their own host name or their own e-mail address?

Braddlee: Their own host name or their own e-mail address?

M: Their own e-mail address?

Kevin Savetz: That would just be something in the e-mail server's software that you are running. I can't think of a Macintosh analogy, but for instance on UNIX, if you... at northcoast.com there are, if there were ten users and you want to add five more e-mail addresses, you just create five more UNIX accounts and there are e-mail addresses that would go with them.

That doesn't involve the Internet, that just involves your host computer, whatever you're using for mail.

M: [Inaudible]

Braddlee: You brought it up, you answer the question.

Kevin Savetz: How do you have a shared resource allocation using Macintosh?

Braddlee: Oh, I don't know for sure [how] to set up in DNS. I know that it is possible because we've done it. I don't know if the Mac DNS will handle that or not. I think actually it does because the folks that I was talking to about it the other day were... the context in which we were discussing it made it sound pretty clear that what they were referring to... that they were using the Mac DNS.

And really when it's a random assignment, it's just a line in the configuration that says...

Kevin Savetz: Pick a number from one to ten?

Braddlee: Right. The first one goes here, the second one goes here.

Kevin Savetz: There's a mailing list that... for people who run Macintosh servers. And I should have but didn't think of it until just now, and if you want to join the mailing list and you can't find it, send me e-mail and I will...

Braddlee: Lets... we'll put it on the list.

Kevin Savetz: In fact, we'll put it on the list, on the URL. Basically it's a mailing list where all people are discussing all sorts of these things about running Macintosh servers and some of these odd, obscure questions.

We have half an hour. We can certainly keep taking questions or we can talk about PGP which isn't an Internet tool per say, but it is increasingly used on the Internet for privacy. We can go either way or we can all go home.

Braddlee: You had your hand up. Why don't you just fire away.

M: [Inaudible] what do you do for a Web server? Is that happening?

Kevin Savetz: That only has to be in DNS. So if you want to be food.com and you want to have www.food.com as one of your hosts, all that has to do is be set up with a domain name.

Braddlee: That's something that's done. Since you're food.com you have complete control over food.com so you set up in your own domain name server.

M: Okay. So no one else can ever have a Web server with that name because you've already got that name?

Kevin Savetz: Because you've got the food.com or whatever. So if you have a Class C address with a small number of addresses, 256 addresses, you can assign those 256 within whoever-you-are.com and however you choose and give them whatever name you want.

You can change them. You don't have to talk to the Internet about it. So that's your address, space. You can assign hosts within those two top... that top level domain and the sub-domain however you choose.

And you can make for example, the same computer can be...

Braddlee: Multiple names.

Kevin Savetz: ... gopher.u.com www.u.com, news.u.com anything of those services that you're providing on that, you can add those names as aliases in the domain service to that particular address.

M: [Inaudible] services. Lets say you're just going to get like a fractional T-1 dedicated line on one of your providers so you're going to want a domain name server [inaudible] what is there available for mail?

Kevin Savetz: There's a commercial mail product.

Braddlee: Is there?

Kevin Savetz: Yes. It's new.

Braddlee: Tell me about it.

Kevin Savetz: But I can't remember the name of it, if you give me your card or I'll give you my card, I will find the name of it for you.

Braddlee: And we'll put in on the Web page after we...

Kevin Savetz: Well I don't know if it's... it's commercial. I don't know if it's going to be FTP-able or even if there's even going to be a Web page for it. But there is, just recently, because one of my friends who is a graduate student, he has this obsession in life which is to set up a fully Macintosh Internet provider. And he was struck with glee when the mail software came out about a month or two ago because that [was the] kind of piece that he was missing.

It seemed from what I remember reading at the time about it that it was real mail software that it was... it would be equal to, like, to Windows NT, SMTP, the software that's available. That it was industrial... it was industrial mail software.

M: [Inaudible]

Kevin Savetz: Is the subject?

M: [Inaudible]

Kevin Savetz: Oh I see what you're saying. Okay. Well, let's dive into that and we'll talk about that as we go through.

M: [Inaudible]

Kevin Savetz: Okay. The subject header is the mail. It goes out. The simple answer to that is no because that's not encrypted.

M: Well, you've got to be careful about what you say.

Kevin Savetz: Sure. And there is... as a matter of fact, you may even want to do some other things to obscure the fact that it's encrypted. It depends on how paranoid you are.

It looks like we're going to talk about PGP for a couple minutes.

Braddlee: Go ahead.

Kevin Savetz: Okay. PGP is, hey guess what?

Braddlee: No, it's... you were just there. Oh, I just couldn't find it. Okay. PGP, this is the text version of the telephone software that we were talking about earlier. This is for encrypting your e-mail and your files. So for example, a couple of ways that we're starting to use this. We

have a number of researchers on our campus who do work with human subjects meaning that they collect data about real living people with real names and real habits such as alcoholism.

They work in a national context. They need to be able to exchange this information across the Internet, either by FTP or as electronic mail. Because they have a responsibility to the people that they're collecting data from, to protect their privacy, this is one of the tools that we're actually suggesting that they use to do this.

Now, that's one example. Another example may be you work for a company. You want to exchange information about your research and development stuff across the Internet. Or you want to exchange details of contracts across the Internet, pricing figures, all this kind of stuff.

You want to be sure that other people are not going to be able to intercept and read that. Sending e-mail on the Internet is quite similar to sending all of your correspondence on postcards. Anybody who sees that mail going past on the wire or if it bounces and gets put in somebody's mailbox by accident, it is going to be... they can read it. You have no protection against their being able to read the contents of messages. That's one of the problems of teaching [T-addresses].

Another issue, which is also becoming important for business is the issue of digital signatures. Digital signatures allow you to certify, using encryption, that the individual who is sending a message or sending you a contract or sending you a price list is actually the person that they purport to be and that that document has not been forged or altered.

So those are a couple of basic things that PGP can be used for. As we were mentioning with *PGP Phone*, PGP works as public key cryptography which means that you have two components that you use to encrypt and send the message, one of which is a public key that I can give away to anybody on the Internet anywhere, anytime.

As a matter of fact, let me see if I can do this, what I do is I leave my public key for PGP up in the Finger information on the UNIX host so that... and this, by the way, is a Mac Finger client. And there we go, that... my information, my Finger information, for some reason it's showing it twice. We won't worry about that, but right here is my PGP public key.

Okay. So I can take this... this is available to anybody. And it has a beginning field and an ending field, the begin PGP public key block, the end PGP public key block. All that gibberish in between is my public key. What happens to anybody on the Internet or anybody who has access to this when I give this to, can use this as a tool to encrypt or sign something headed towards me.

So, if I go back into PGP and PGP was originally written for DOS, and through this current version which is 2.6.2 the port to Mac is fairly crude. It's actually better and easier to use I think than the Windows version, but it's still pretty rough.

Version 3.0 which is coming up probably in the next couple of months will be much more graphical, being completely rewritten for a graphical user interface, both Macs and for Windows.

So let's say I want to send somebody something. So I use the encrypting sign which means I'm going to do both functions... two functions. I'm going to encrypt something and I'm also going to sign. We're going to steal something off of Kevin's drive.

Kevin Savetz: We'll go into... well does it have to be a text file?

Braddlee: No, it doesn't have to be a text file.

Kevin Savetz: All right. I'll go into docs and grab a random article that's signed.

Braddlee: Pick a year and it can be a... pick a FAQ. Yeah.

Kevin Savetz: Sure. It's huge, but that's fine.

Braddlee: Take that file. That's fine. They're just text files. Okay. Now this will work both with text and binary files, so for example, didn't find your secret. Oh sure. I know where it is. It's over there.

Hang on. This is going to take a second. I bet it's not going to be simple either. The secret key is in a different folder. I know where the public key is but not the secret keys.

Kevin Savetz: Yeah.

Braddlee: Sorry about that.

Kevin Savetz: So you feed it a text file that's produced in a word processor?

Braddlee: That's right. You give it your public and your private key information and it encodes it. It creates a separate file which is unreadable to you. As an option, you can have it delete the original if you want, so you can make it secure. And then you have this encrypted file which you can either keep on your hard disk or you can e-mail it to somebody. It can be a text file or it could be a binary file or whatnot.

And then if you send it to somebody else, then they need... if they have your public key, and they have their private key, then they can then decrypt that message and look at it on their system.

We're going to try to demonstrate that.

Kevin Savetz: And feel free to keep talking.

Braddlee: I will.

M: [Inaudible]... conversation between a real estate broker and a bank [inaudible] was encrypted, can they force the people to deencrypt?

Braddlee: If e-mail is encrypted, can a court force... can it be either... can the court force them to deencrypt it or can they just do it?

First of all, regarding general non-encrypted e-mail traveling over the Internet, it is very easy for someone with a court order or just even a nosy system administrator or a company that wants to check their e-mail to read all your e-mail that you haven't read yet or the stuff that you saved. Really easy. Stuff that is encrypted, however, PGP gives you several... you can give it a light encryption, you can give it a medium or a heavy dose of encryption.

If you give it the medium or the heavy doses... I don't know what it's called, it is impossible for anyone to decrypt it. The court can probably throw you in jail for the rest of your life if you don't type in your secret password and decrypt it for them, but they can't do it. There's absolutely no way that they can decrypt information behind your back without your code... without your private key.

Kevin Savetz: However, they can subpoena your private key, and one of the reasons that Mac PGP, the new version of it will have two secret keys will be that there will be one that you will use for signing things and one that you will use for encrypting things. That way, if for some

reason the one that you use for encrypting things has to become compromised, for example, because something was subpoenaed, then you would still be able to continue to sign things using the same secret key and not have to change your keys.

One of the big problems about this is key management. Giving people your keys, getting people's keys from them, finding out whether the keys that you have are real or invalid.

Braddlee: There's some key surfers on the Internet too.

Kevin Savetz: Right.

Braddlee: So if you want to send private e-mail to Braddlee but you don't know what his key is, you can go to the server and search it and see if he has registered himself.

Kevin Savetz: Yeah.

Braddlee: And if so, you can then find him and send him private mail.

Okay. So we're going to try this again. I think this has to do with the fact that I'm trying to run this on a floppy and it's just not very happy with me.

Kevin Savetz: Anyway, it would work really well. But honestly, it's not... this is a program that is not real polished as Braddlee said.

Braddlee: Yeah.

Kevin Savetz: And it takes a little bit of tweeking to get it running the first time. But once it does, and assuming you're not trying to use it on someone else's machine...

Braddlee: Right. It's like I can do this over here very easily but this one won't plug into the video. I use it all the time over here, however. It works. Trying a floppy, I apologize.

Kevin Savetz: So basically that's PGP, not an Internet tool but useful for private communications on and off the Internet.

Any questions about PGP or anything else? Pretty much our canned spiel is done so we can pretty much go in any direction at this point.

You have us for another fifteen more minutes of unbridled Internet joy.

Braddlee: There are a couple of other things that we haven't really talked about. If anyone is interested in a relay... an Internet relay chat, there's a program called *Homer*.

I have to admit that IRC isn't really one of the things in life that I find especially useful. It's generally speaking, a lot of people sort of saying "Hi, how are you?"

Kevin Savetz: "Are you male or female?"

Braddlee: Yeah. "And can you prove it to me?"

But IRC is a very nice IRC client. There's a URL for it there. It does some neat tricks including it provides support for speech manager which means it will do text to speech translations. So if you're familiar with the Marvin and Marly voices from Mac AVs, you get to have Marvin and Marly voices for your IRC so you can actually "hear" the people who are typing at you.

It also supports a faces database which means that it uses some of the lower-level IRC stuff to move an image so that you can have an icon or a photograph of yourself up along with the other things on the IRC channel.

That's not interoperable with other IRC clients other than *Homer* because it uses some stuff that's basically code written, customer code written for *Homer*.

But if you like IRC, that's pretty much, I would say, the only client...

Kevin Savetz: Yeah. There was *Uncle Orde* for a while but it's not nearly as nice. Other random tools... I think I have it here. There's a program called *MacWeather* which is a nice little interface to the Weather Underground that we were looking at earlier.

This just kind of Macifies it and gives you just the weather information is just about any city that you can name. It's going to open the connection. It tells you the wind speed and the barometer and the temperature anywhere.

Here's the temperature in San Jose and the wind speed and for some reason it couldn't get the barometer information so it leaves that blank. And we can change the location. I don't know... lets get... state, lets pick some place. Might as well pick Boston. It's going to get something weird, but I got uncreative at the last minute there.

Now it will update it and we'll find out if it's raining in Boston.

Braddlee: There we go.

Kevin Savetz: Yeah, it is.

Braddlee: Hey.

Kevin Savetz: So it's a cute little thing. You would have an update every ten minutes or something if you want to track the weather. And yeah, you can also [see] the forecast... where is that.

And so you can get a text forecast, and this is the same stuff that your weatherman uses on the radio. Tonight rain, drizzle and fog, low 45 to 50, wind east 10 to 15 miles per hour, chance or rain 90%.

So that's *MacWeather*. It's in the handout and it's a fun little quickie program.

Braddlee: And as far as Usenet, news readers?

Kevin Savetz: Oh yeah, we kind of...

Braddlee: There's a problem with that which is that because news is something that usually your Internet service provider provides to you as a service. It's not the kind of thing that you can go out and like look at anybody's news server. Because this is a temporary network, the news is not something that they're providing locally.

And they're not really able to serve half the news server to provide news to this IP, so that makes using that software a little bit limited.

Kevin Savetz: There are three good newsnet news readers for Macintosh. My favorite is called *Newswatcher*, it's freeware. The URL is in the handout.

At the last show, we showed off *Newswatcher* and you liked the one called *Internews*.

Braddlee: *Internews*. Yeah.

Kevin Savetz: And we fought over which one was better. I used his for like three months and then went back to *Newswatcher*, so I guess I'm not a big convert. So *Internews* and *Newswatcher* are our two favorites. And if you need to use Newsnet news, download them both and try them out.

Braddlee: Yeah. *Internews* is slightly Eudora-like in terms of how it lays things out. And I like it because it's very flexible in the things that it allows you to do. There are a couple things about it that are a little bit clunky as far as how it indexes news groups. There are a couple of things that *Newswatcher*, *Internews* does when you first set it up. It can be surprisingly slow. But once it's up and running, I kind of like it.

And there's another one called *NCS* that a lot of people like. I've never been particularly in love with it and I gather it leaves you...

Kevin Savetz: Me neither.

Braddlee: ... as well, but other people swear by it. And all three are listed in the handout.

Kevin Savetz: I think we are done. If you have any more questions, feel free to come up. Thank you for coming and have a safe trip home.

TUTORIAL LOCAL BUSINESS WEBS

SPEAKER

R. Taylor Walsh

Washington Information Services

R. Taylor Walsh: [I'd like to welcome everyone to this session. The organization that I work for is called Washington Information Services,] which means it was designed to serve the public service enterprise across the metropolitan Washington area. It started in 1993, before there was a WorldWide Web; but [once] we started in 1993, basically schools, libraries, and local governments all got on-line. You're probably aware of organizations like mine elsewhere around the country; there are 250 or so around the country that are in formation or operation. In any case, many of these community networks have formed the basis of what we see happening now in the metropolitan areas on the WorldWide Web. We'll take a look at a few of them in just a minute.

What I wanted to do today — and I don't think we're going to take the 2 1/2 hours allotted this morning — but I want to give you an overview of the landscape of metropolitan area networks and what's happening there, and some of the trends and some of the forces that are in play right now. The whole local enterprise is changing dramatically, as we'll see. It's funny, because local areas, and local businesses in particular, have been the last holdouts as far as wanting to go forward and consider on-line services, whether it's the Web or anything else, as anything they would spend their time tending to or considering.

As the on-line services have grown over the last decade or so, local markets have been pretty much quiet in terms of a local business making itself available or making its information available; and I think you see that the WorldWide Web, just like it has for business in general, has now energized local businesses and local organizations.

We're now seeing a rapid deployment of WorldWide Web sites in metropolitan areas. In fact, if you go out on the Web — as we'll do when we go around — you'll see that the speed with which this is happening is truly astonishing. The number of businesses and the number of organizations who are trying to stimulate the appearance of businesses on the Web in local markets has gone up very quickly, very quickly indeed.

The background for all of this is that, oddly enough, when on-line services and electronic information services first appeared, when there were the first endeavors by big media companies and telecommunications companies to try to put local businesses on-line. You have to go back to the late '70s and 1980 when [Viewtron], which was a Knight-Ridder and AT&T project in Florida, tried to do this, and Gateway, which is out in Los Angeles, [also tried it] when the Times Mirror Company put together a local service. And these services not only tied up your telephone, they tied up your TV at the same time.

They didn't work, and because they didn't work and because so much money was put into them the newspaper industry in particular, which had been looking at the Knight-Ridder and the Times Mirror experiments, basically were terrorized for at least a decade in terms of what they wanted to do in getting into on-line services. And newspapers, of course — when you talk about a venue for business in a local market, the newspaper has always been, along with the Yellow Pages, a prime venue for businesses to get their marketing messages out — along with television, of course.

But the wide, broad, regional story of any community has been woven together, in many instances, primarily by the newspapers. In the newspaper business, the list of trends shows that newspapers are coming back into the on-line service world. They're using America Online or

Prodigy, or they have CompuServe in the last couple of years, and now they're also moving into their own Web server space for the same reason that other publishers have also decided to deploy WorldWide Web sites — because they can control the contents, and the look and feel and the relationship with the reader or subscriber, as opposed to using America Online or CompuServe. They control the look and feel, they control the space.

There's a huge dichotomy there. If you're a publisher you want to control all your relationships; however, America Online, for instance, has four million subscribers who know how to use a modem, and that means if you have a newspaper you don't have to teach those people how to use a modem to get to your stuff.

But that has all changed dramatically in the last year. In addition [to what I said earlier] on the background, the first bad experience that newspapers and big media companies had [was in the early '80s,] so they basically went away. In the meantime, what we saw were a number of factors that have taken us to this stage today, when we're talking about businesses and local markets having been reluctant to put anything on-line. Few have done anything even as extreme as open up a bulletin board.

You know, a technology company might have had a bulletin board where you could in to get information about services. [There were] other factors at work through the '80s which have brought us to this point [today], where the Web is not just a visually-pleasing place to put your stuff. You also have an enormous marketplace out there right now that is ready to take advantage of it, but only because in the last ten or twelve years the work of the on-line services companies have given people — individual users — a place to learn about this medium.

Bulletin boards... Certainly, in local markets, the local bulletin board community was really the first incubator for a lot of this experience. And, of course, in the early days technology was primarily PC-based, so [bulletin boards were] oriented to technology and were not connected to anything else very much unless there were networks of bulletin boards. Simple, stand-alone, one to four line bulletin boards were connected in some networks like FidoNet, which was a network of bulletin boards and educationally related bulletin boards.

So you had a very rickety infrastructure in the '80s that began to take shape. The local bulletin boards had people who used America Online or CompuServe or Thesaurus, which was the first national on-line service. which is where I got my start. I was there for six years in the early '80s. These are the companies that provided a way for people with PCs and modems to get into this business; and everybody, of course, was working from home or from their business in some local area.

And at the same time the Internet, of course, in its rendition as a research and education infrastructure, was also emerging in the early and mid-'80s, serving a very defined group of communities — but again, building a user base of people who would eventually become able to use any kind of resource on the Web or the Internet. And then in the mid-'80s you also had the emergence of community networks.

Now, I've put a little time chart together — I think it's the last page on this handout — that shows you, in general, a timeline of various events that have taken place up to now. You see we talked about local bulletin boards over on the left there, and about the 1980s time frame, and the appearance of the early on-line services; then up above the line the community networks. In about 1985, the first community networks started to appear.

Community networks were different from bulletin boards that might have been devoted to a Mac-user group in a town, or a PC-user group, or a Dungeons and Dragons role-playing group or whatever. The community network was designed from the outset to encompass the entire region or an entire metropolitan area's region. Cleveland was one of the very first, [with] Cleveland FreeNet. Before that [there was] the Santa Monica Public Electronic Network. We had a handful in this time frame. Colorado Springs had Dave Hughes with his network, and

those were bulletin boards in the sense that they were either DOS or UNIX-based bulletin boards designed to give local governments and teachers and schools a place to go, to begin. They were designed specifically for that purpose, and since 1985 there are, as I said, a couple hundred, 300 in formation around the country.

Now they are all part of what is now, in any metropolitan area, a much broader, much more interconnected web — not world-wide, but a local web. And when we put CapAccess together in 1992, at that point local dialogue on the Internet was basically non-existent. There really wasn't any. PSI and UUNet were coming along, offering some kind of dial-up service, but the WorldWide Web was nowhere in sight.

One of the things the community networks did, one of the points of connection that was made, was in about 1990 when the Internet itself became the focal point of what has turned out to be the National Information Infrastructure, and [also] today [with] the federal government's program to develop a National Information Infrastructure and put funding behind it — at least so far as they don't put the Department of Commerce out of business, which might happen. Basically, Senator Gore, when he was in the Congress, pushed for the development of this National Information Infrastructure, building on the networking that was already in place in the Department of Defense, the Department of Energy, NASA and the National Science Foundation — the federal Internet. The Internet's roots, as you all know, go back into that collection of interconnected networks.

What Gore did was extend it and say that we need to give schools access to these resources, that we need to give the public a bit more access. Now, the Science Committee, just as a small diversion, didn't realize in the late '80s that it wanted a national research network, and they didn't particularly want a national research education network. However, when this initiative was launched and passed by the Congress it energized all these teachers and school people and very, very special librarians in the public sector who had been on-line for eight or ten years, who knew that their world was going to change dramatically. And because that was so, they raised hell with the federal agencies and said, "Hey, we want to be part of designing and developing this research network and education network, so let us in."

And the science guys said, "No, go away." But the net effect was that the influence of the public sector expressed itself many times in these early community networks that were locally oriented and all interconnected to the Internet, because, in general, the home for their technology and some of those districts were local universities that gave their services in time shares, technologies or Internet links. I can speak from our experience at CapAccess in Washington — George Washington University was the entity in our area, and the institution that made possible this little collection of organizations to get going.

So you had this convergence, you had this Internet growing up and you had the users of bulletin boards and on-line services sort of colliding in the late '80s to 1990, and converging with one another. The forces that encouraged the development of community networks were pretty much secured, and enough of the cost of the technology had come down and anybody thought that if they could run a UNIX bulletin board on a 486 with a few phone lines they'd be in business. It's a little bit more complicated than that.

Now, if you follow what's happened in the last couple of years, particularly in the last six months, even if we just look in our neck of the woods in the Washington D.C. area, the change is pretty profound. WETA is the largest public broadcasting entity in the Washington area, and it has radio and TV, and they produced *The Civil War* and *Baseball* and other stuff that I'm sure you've seen on [public] television. In September they acquired CapAccess, becoming the largest public broadcaster to have a community network in-house. They have a radio station, a TV station, and they've got a community network.

Other local public broadcasters, including WGBH here in Boston and elsewhere around the country, have been looking at community networking and trying to break their own paradigms about what business they're in, in part because of the Department of Commerce's programs to fund community networks — they are more and more involved all the time, and the local public broadcasters are more involved. You'll see more of this at the federal level. The Corporation for Public Broadcasting and PBS have been developing their own Web sites and their own on-line service capabilities. There's such a thing as "PBS On-line" out here in the world, and the importance of this is that the community network, the nature of networking, and the interaction between citizens and among groups and institutions that characterize community networks now comes into the public broadcasting infrastructure.

And what it does is a couple of things. CapAccess, in the two years of its little rickety start-up period, was able to offer not very great technology; it was a UNIX dial-up bulletin board primarily delivering information in ASCII text format. We could have gone to the Web directly, but we didn't. Why? Because there were a lot of people out there, oddly enough, with Commodore 64's and 1200 baud modems, and they're still there, and as a principle of operation we said, "As many community networks have done around the country, we have to be able to serve those people whatever they happen to have."

So you see, as a result some of the late developing community networks such as LibertyNet in Philadelphia and a couple in Virginia, that they've decided to put everything into the Web format, and if it's text then to go with links — which, of course, is the text rendition of Web-formatted material. CapAccess got started before the Web was even a mote in a network of God's eye. It was burdened, if you will, by this text presentation style, but there is a Web site that CapAccess has put together, and this is kind of a prototype; it's not very exciting, because why would you spend much time on it? It will change dramatically in the next six months.

In 1995, in September, WETA acquired this resource; and what it is more than a resource, it's a new way of connecting in the community. Public broadcasters like WETA will now have a relationship with the public sector, with local schools, libraries and local governments and non-profits at a level it never had before. As a broadcast medium you're not involved in helping your users invent the content and material; that's what a community network does, it provides a place for people to play. And just like any good site does, this is going to change their business in the local markets.

And, of course, the added factor to that is that public broadcasting as you probably know it is under tremendous financial strain. They're all planning on the day in two or three years when they have no more federal money at all, so they're going to be driving like crazy to do public/private partnerships in their local regions. WETA, like most long-time public broadcasting entities, has very good connections in the grant-making community and the private sector, and I think you're going to see that one of the upshots of this is [going to be] some interesting new financial arrangements and economic arrangements [that will] fall out of this. And new partnerships, too, because the underpinnings of public funding for broadcasting, to say nothing of the public libraries, is all in upheaval right now. So we have to come up with new ways to fund what has been, in the past, public media.

The other things that have happened rather quickly in our area — and though I think it's just in the Washington area, [it is] emblematic of what's going to happen elsewhere — what is happening is that the *Washington Post*, which is a big paper in Washington, has its own service up called *Digital Ink*, and America Online has launched a local service called *Digital Cities*. The first one that they've unleashed is in the Washington area, and you'd have to be an America Online subscriber right now to participate in it. They very much want to go into the

marketplace and sell advertisements to organizations in the Washington area, and then Philadelphia and Boston and wherever else they're going to do this.

And what [America Online] says to their advertisers is, "The *Washington Post* just got launched and it only has about seven or eight thousand subscribers; we at America Online have 120,000 America Online subscribers in the metropolitan Washington area." And they'll be able to say the same thing proportionately as they go to New York and elsewhere, so they're saying, "We have a leg up, we want to be the focal point for business activity in the local area."

This is getting to something which is mainly confusion in the local marketplace, but that's what America Online is doing. PSI, which is out here, is one of the fastest-growing Internet access providers. They're very aggressive Internet access providers, [and they're] launching a local service in Washington as well in the next month or two. And then, around the first of the year, Bell Atlantic, the local telephone company in the mid-Atlantic region, is going to become an Internet access provider and bundle that with — guess what — local information service.

So it's very crowded out there in the local marketplace in the Washington area. On top of that, you have other entities in the local marketplace who are working to put organizations and put businesses on-line, and serve as sort of hubs for businesses, like the *Business Yellow Pages*, and we'll see some of those in just a minute.

I think this is all for the good, and with the arrival of the phone companies one hopes it's going to mean that access to the Net is going to fall and plummet in price. You never know; but the other factor, I should say, is AT&T's personal Internet service promises to bring access when AT&T becomes another access provider — and there are apparently no legal restrictions for them becoming local access providers. And the other factor is the cable companies; they're desperately developing the means by which you could hook a modem up to your PC and hook it into your cable connection and then be on-line at 10 megabits.

And so there's a huge race by the phone companies and cable companies to high-speed access into the home and local businesses. In many places the cable companies are — and have been for several years — laying fiber along their right-of-way, [along] their traditional drops which have been in residential neighborhoods where they really placed their stuff; but now they're also moving their drops into business areas as well, because they can see that there's a tremendous opportunity to serve business customers in their region.

I think we see this in the D.C. area and I think you'll see it all over the place. The bottom line is that there are just a hell of a lot of places to get access and a hell of a lot of companies that are going to come into businesses and say that they have solutions, and the companies, I think, are going to be slightly confused. I have a little scenario there on the first page which takes a hypothetical business person through the thought processes for thinking about being involved in this WorldWide Web.

This is a guy who's got two or three audiovisual sales and repair stores, and has an AOL account because his brother told him he has to get one so that they can e-mail each other. His kids use it in school, he's heard all about this, his guys are selling computers and he needs to get on the Web someday — and he doesn't know what to do. And I think that despite what we'll see as we go around the Web and take a look at what's going on in different regions, I know from my experience in talking to people in the Washington area that there's a feeling of, "Yeah I read a lot about it," and he can't go into a bar or men's room without seeing a newspaper on the wall with the Internet all over it.

He doesn't know how that's supposed to affect him or what the benefit is for him; and for those of you who are in the development business, the local marketplace has become an opportunity, if it's done right, to help solve those problems, to help sell that person through those questions that he has, he or she has, into whether they ought to be in this infrastructure.

I think the driving thing right now is "Because everybody else is, I've got to." For some people that's sufficient motivation, but for others, because of the cost involved or because of the hidden costs that you don't count on, that could be their other factors.

M: [inaudible]

R. Taylor Walsh: Well, you better get on it.

M: [inaudible]

R. Taylor Walsh: Yes, it is. Okay, thank you. Have a good flight. Incidentally, please interrupt at any and all times.

M: I have two questions. These local community networks — are they primarily focused on providing public information to citizens and Internet access to businesses, or do they also allow businesses to advertise and sell their products and services?

R. Taylor Walsh: **Did everyone hear that question? Is the role of the community network to provide citizens access to public information, or to provide advertising in a place where businesses reside? Does that pretty much get it? The answer is that it depends on the community network and what it thinks its philosophy is and its mission is. It also depends on the financial practicalities of trying to run what were really free services offering free Internet access, as many of us who were involved in that part of this equate it as and try to do. And part of this was a philosophical approach that what we're trying to do here is replicate in cyberspace what public broadcasting and the library offered in those other media.**

You can only carry that so far, and it's not very practical to have SLIP connections for nothing; somebody has to pay. So what we've seen in the last year and a half or so is that some community networks like CapAccess have had to say, "Well, we took free access as far as we could and now we have to charge you \$25 for an account." Others have gone to a monthly fee, a sign-up charge and a monthly fee, and others are looking at a text access for one fee and Web access for another. LibertyNet in Philadelphia has decided it wants to provide space on its system and lease its space and be a service provider for everybody, even though they're a community network in the broadest sense.

Most community networks were designed for the public enterprise. LibertyNet wants to have small businesses be able to put their stuff up on the Web and be an incubator and host for that. What CapAccess is doing and what others are doing is acting as a service bureau for organizations in public service. Large county governments, library systems, school systems, and non-profits are taking their first steps into cyberspace through CapAccess, and we're charging a fee for that. When you get into this business you have to know that at some point every organization is going to have their server tucked over in a corner there at some point.

The schools are already beginning to see this. School systems are integrating their server technology in with the heat and air conditioning, as it should be — it should be part of that fabric of their infrastructure. In the meantime there are still thousands of organizations, particularly non-profit ones or large local governments, who know they've got to get into this but don't want to make the full-bore commitment of purchasing equipment and dedicating the people and all that stuff on the technology side. So a server farm, if you will, a collaborative effort which is what these community networks are, gets them going and gets them up and running.

And you see the real issue here is not so much technical; everybody says [the issue] is the people and it's true, and here's where it's true: in the back end of a local government. Let's look at the public information officer of our county government, who manages the content that appears on their site. She has a lot of work to do in dealing with people in other departments to get the information from them and get it up on-line; so what you have is [a situation where] the relationship she has had with those people, her peers in local government, that changes. The relationship that the local government has with its residents and its citizens, that changes. So internally, the staff of the organization also gets access to the Web and the Internet and all those resources, and they get to learn how to make use of those resources.

Those are all very important components of this, so it's more than just putting up information so residents can come and see what the parts schedule is for next week, which is pretty mundane and everything. So that's where the real key lies in giving those organizations a way to do that on a cost-effective basis; it's the objective of CapAccess in our case, and [also the objective of others] elsewhere around the country.

All these community networks reside in a twilight zone financially. They are serving what will come to be more; they're doing the job that local governments, libraries, etc. will pay for and integrate into their own system over time. But right now — and those entities, even though public funding for everything is really under a lot of stress right now, at least there's a traditional, financial underpinning that can make that happen. Community networks don't have that underpinning, so efforts to raise money from corporate contributors and asking people to donate money and all those things, and trying to replicate the public broadcasting model, hasn't really worked.

Public funding is drying up and contributions are very tightly under competition, so that's why you see the movement of CapAccess into the WETA structure — because that's the way it needs to go. These community networks need to find a benefactor and be incorporated into the mainstream public media.

But the important thing about them, or one of the important things about them, is that I guess 25,000 people have passed through CapAccess in the last 2 1/2 years to register as users. I think some of them have gone off and then registered with Internet access providers separately, but what they have done is — and I should say that many of these users are folks who just got a PC and a modem last week. They reflect the new category of user in all of this, the new level of the market that Steve Case of America Online is always talking about. They're interested in the next 93% of American homes that are not on-line, and that's what they want to prepare themselves for.

Well, a lot of those people are getting their first taste of this through a community network that costs them next to nothing to join, and then they get to e-mail all over the world and they use Gopher and ListServ — which are not the wonder of the Web, but they're very powerful, as anybody knows who has done this.

In terms of a local marketplace, businesses now are looking at [the question], "Should we do something because of the work of community networks, which have built up a little base of users and potential buyers or whatever?" They want them their market, because they play that very important role. All of these are interwoven together, so that's how that has been playing, and it's also, of course, in great change every day.

As we'll see, in most communities you don't have one entity; it's not — there are no entities trying to be the hub for the index, the Yahoo source for everything in their territory and their region, all about businesses or whatever it is. What you find is that there are probably a

half dozen organizations that end up playing that role, and that's fine because there are many places to go get a list of who's doing what.

I think we'll find that we're in a period right now, however, where it's still hard to find the searching capabilities. People, out of the kindness of their hearts or in the interest of building a client list, will put a list together of businesses, and it will be a list of non-linkable names — because presumably what they want to do then is take their list out to the non-linkable auto repair guy and say, "Look, you're on the Web, all you need to do to get active is to pay me to build a Web site for you." And that's fine, that's going on.

Let me just ask you all, are you here as developers? Who are developers here? Okay. Why else are you here? What are you here for, sir?

M: [inaudible]

R. Taylor Walsh: What did you come to this session hoping to find out? Anything in particular?

M: [inaudible]

R. Taylor Walsh: Ma'am?

W: [inaudible]

R. Taylor Walsh: Okay. Sir, how about you?

M: [inaudible]

R. Taylor Walsh: Okay. Sir, developer?

M: [inaudible]

R. Taylor Walsh: Really? Jones, cool. It's a big pie, and everyone should jump in and cook one.

Okay, let's take a look at some of these sites so we can see the multiplicity of uses. There are a number of places that have done a good job becoming a primary link to lots of city services around the world. CityNet, I think, has done a pretty terrific job. As you see, this is their Home Page, and they have made it a world-wide, global effort, so if we choose the United States here they've got it broken down by state.

Let's go to Oregon, and we're going to pick Portland. Now, when I first looked at this I was pretty much astonished that this many cities in Oregon had any kind of Home Page-related reference to them. Some of them are in standard Internet style — entrepreneurs out there will just put together the list, whether anybody in the city or town knows about it or not, and then just follow up.

So again, all this is under CityNet indexing and categorizing here. And so if we do the Portland, Oregon Web Directory, this is, I believe, one of these examples of a company here called Spire Communications; this is probably the Home Page, and they have put together a comprehensive — they've tried to make a comprehensive directory here of businesses in the Portland area, and of course browbeat the visitor right here by saying, "If you're not on the list you've got problems, so create your own Web site," which they will be glad to help you do. If you go through this, they probably may be just one guy, so he's going to charge you \$35 a business to set up a couple of pages.

Let's watch the text there; it tells you what he's going to do. Here's an example of a list of businesses put together by one guy in the business, not associated with anything, really, but himself. Here's another list of Portland-area businesses on the Web, and another Internet provider. And you'll see this in just about any area you go to; you're going to see a developer that takes the initiative to put together the list.

Now here, I think, this is an example of — there's no search mechanism in this thing, and in most of these city listings like this you don't find any search mechanisms. The way we [solve that is to] have a Net search locally, and I think this hasn't been done yet.

So here's Days Inn, and I also should mention that these pages sure are coming up nice and fast, aren't they? I'm told this is a 10-megabit Ethernet connection; it's maybe not that fast, but anything you guys can do to get 10 megabits to all of our wrist watches, by all means please do.

M: [inaudible]

R. Taylor Walsh: This year ends in 58 days. That this year?

M: [inaudible]

R. Taylor Walsh: In Alexandria? Alexandria, Virginia, is a suburb of Washington D.C., and for some reason it's a hotbed for development of all kinds of technologies.

M: [inaudible]

R. Taylor Walsh: So here's a vendor who — I'm not sure that Days Inn does it, but if you look up at the location site this tells us that a developer will do that and put this up on-line. I saw the corporate Days Inn also has their own site out on the Web somewhere. Okay. Yes?

M: [inaudible]

R. Taylor Walsh: Kind of reminds you of when companies were buying PCs behind the MIS guy's back and putting them into companies. I think that a lot of that still applies; I don't know, I think it depends on each organization. How is this a problem for the Royal Bank?

M: [inaudible]

R. Taylor Walsh: I think it's — from what I've seen, I have not seen a lot of violations. I think people on the Web, in the Net world and particularly on the business side, are pretty straightforward. There's always someone trying to register *exxon.com* or *gulf.com*. I think we're passing through those phases and that kind of stuff; but it is an issue, and I think it's a communications business, and if you're communicating with [people] internally then that kind of thing shouldn't be a problem. It depends on the culture of the corporation, I think. You always have entrepreneurs out there saying, "That doesn't matter, they'll figure it out later, you'll be a leader, you'll show them the way and be a champion internally." Whatever.

A subject I wanted to get to, but we might discuss it now, is of considerable importance as this goes forward, and that is the role that this structure is going to have on banking in local markets. I have a client in the Washington area that's got a bank with five or six branches — actually eight, I guess, with Baltimore — and I'm still trying to come up with a coherent explanation for him about what all this is going to mean to him as he goes forward.

And if you have got your *Quicken* and your *MacInTax* that Intuit has delivered to you along with a *Netscape* browser — they've just done a deal into Netscape — and the electronic banks are out there, some of the intermediary roles that banks play are under some kind of change. I don't know the extent to which there will be a lot of change. Have you guys looked at the relationship within Europe? I assume you're one of the largest banks in Canada.

[Tape change]

R. Taylor Walsh: [I'll] see if I can find... First Union, of course, is a major bank, particularly in the East and Southeast. They have also been very aggressive in developing this site, and they've got a service mark on cyberbanking, or so they say. What I want to click on here is this thing called "Community Commerce."

M: [inaudible]

R. Taylor Walsh: This is a time to combine root words and service marking. To me, one of the interesting things is that here is yet another entity helping other businesses get on-line, and playing the role of the place where people get on-line. The bank becomes your Internet service host — that's what it looks like they're trying to do. And extending that relationship, the bank's business relationship beyond account management and deposits, into another level, a whole different level of business relationship — that's very interesting. It's almost like whoever gets there first is the one who's going to pull away with the business, although this is such a decentralized infrastructure that we may see, in every different area, scores of organizations being able to do this.

Whether AutoNetwork or PCTravel is going to be satisfied with the way the bank does their Web service development remains to be seen. This probably is not the bank's business; I think [it's a business for] a service bureau for information or advertising or marketing stuff for clients. But anything's possible in the future, right?

W: [inaudible]

R. Taylor Walsh: Do you have fiber all over the place?

W: Working on it.

R. Taylor Walsh: Another one — I think I've got them listed as unsung entities out there or something — the power companies have got infrastructure that can be used for this. I think the key is that the bottom line of this medium is that it offers relationships, just rips them up and tears them apart and rebuilds them all over the place.

And here's an example, an AutoNetwork. If you've got to get a loan to buy a car, where will you go? To a bank, there's a way to reestablish or reaffirm relationships that make sense financially for a business in a local marketplace like this. Of course, the dealership is local because you've got to go somewhere — it's got to be on a corner on a street with an intersection, where you go buy it and pick it up. But the bank, First Union, is down in Charleston, somewhere down in North Carolina, and their operational end does not have to be in your metro area.

Now, does this compete with my friend and his bank with eight branches in between Baltimore and Washington? Does this mean he's going to have less opportunity to make auto loans as a result of this affinity relationship here? Maybe; that's the kind of thing I'm trying to

work out with him. How do you get in the way of this electronic cash stuff? It's very important in local banking's financial affairs, I think. I don't know specifically how yet, but... Yes?

M: [inaudible]

R. Taylor Walsh: If you're PCTravel? Well, you can block any links from anywhere, and you can block addresses. You can do blocking. The whole question of who gets to go where and everything is still up in the air; this is still too much in the formative stages, and I think a lot of people don't want to do a lot of blocking, they want to see what's happening and encourage this connection. But I think it's a good issue in the future.

W: [inaudible]

R. Taylor Walsh: What do you gain by blocking? Well, you could have a site that's designed really only for a specific set of people, but if somebody takes your image, that PCTravel image, and puts it on their server on their Page — which they can do — and then put a link to it, it may, I don't know... There are reasons for people to want to restrain or keep the flow into their site controlled.

M: [inaudible]

R. Taylor Walsh: Guilt by association, Net guilt. Yes sir?

M: [inaudible]

R. Taylor Walsh: There's a good question. The answer is that I don't know what the liability is in terms of links.

M: [inaudible]

R. Taylor Walsh: Well, presumably, in this case First Union has control of this Page, so they presumably know what's behind those little boards there and they know what's going on and they want their customers who come in to go there. No doubt there's probably a financial reason for them to want to direct you to these guys over here; maybe PCTravel is a big client of the bank, and they do some kind of financing of trips. Who knows?

But what that says is that you need to be vigilant if you're going to do this. I think one of the things that's often underestimated is the amount of work it takes to really run one of these things well, and how many people it takes.

Earlier this week, over at one of the other hotels, there was a two-day marketing seminar, and on one day they had the fellow who runs an ad agency called Modem Media talk about their experience in putting together a page for Zima, which is a clear alcoholic beverage that one of the brewers has put together.

And if you ever take a look at the Zima Home Page, they've done a very nice job of creating a community, which is a key to a lot of this — creating a relationship with your customers and the people in your universe. You want them to feel like they're part of whatever you're doing. And they have used a lot of techniques to really do that, really very well. They've got six to eight people who are doing that for one client, all the time. In a traditional advertising setting you may have a television production crew and producer who may produce a TV ad in

30 seconds that may take eight people three weeks to do it, but they're not doing it all the time.

So there's a dimension of support that really is just beginning to be understood as being pretty crucial. Yes?

M: [inaudible]

R. Taylor Walsh: Well, my view on that is that personal computing, with the accent on the "personal," is at the heart of all of this. I was going to start this by saying that my biases were that the Internet wins and the interactive TV loses, and that the power in all of this resides in the PC and in the server — I'm sorry, in the browser and in the server. And those components become less costly and more capable over time.

And if anything, you put power into the hands of a classroom and these kids are doing great stuff with all this stuff. And they want it; they want the control and the power to be able to tell the story of their school. That's what it amounts to. [They also want] the ability to connect with other schools around the world and do joint projects on whatever it happens to be.

That's what the Internet makes so easy and available to everybody, and why it's so powerful. You don't have to... Okay, you've got the class and the teacher's got to say, "We're going to do this project for sixth grade science essay on some subject, and we're going to join with these other schools around the world." So you've got that framework, but the phone company's not going to tell you to go there or go here. Yes, I think they're going to want to have it big time.

I was at my kids' back-to-school night a few weeks ago and they've got a great lab with a bunch of PowerMacs in it, and the parents all got in and the computer teacher was talking about this and a guy shot his hand up [and asked], "When do we get a Home Page?" Every school wants to have a Home Page, lots of classes want to have Home Pages. So it's controlling and telling the story about you and who you are and what you're part of that's the driver, and the tools are what make it possible to do that.

M: [inaudible]

R. Taylor Walsh: They just vanished? As I said, vigilance is something of a Net liberty. I know that that's not true. They've changed the address, so let's see what they have done. The Marino Institute in the D.C. area has come into being in the last year to try to play a coordinating role in the community network side of this business, and they are concerned with not just putting a school on-line or non-profit on-line, but whether or not doing so has any beneficial effect. So they're trying to provide some measure of measurement to the use of this technology in these settings. One of the things that they put together is a directory of public access networks, and I think I just put a couple of things on one of the last pages there that included the address to this site; marino.org will work. We'll get to that page we just saw, and from there even go here.

Again, we're talking about local business webs, and the role that public access networks or community networks play is going to become much more entwined in business settings. The network takes down walls that have been traditionally established institutionally and socially and every other way. So here's a little map, and you can click on the map if you want and go out to Montana — this alleged 10 megabits is great, isn't it?

Here are some community networks out in Montana. Sky Telegraph is one that's been around for a long time; it says 1988 here, but it's actually more than that. They are an outfit that has done a terrific job in getting schools — out there schools are separated by scores of

miles, and they early on traded a bulletin board network of schools that served as kind of a foundation for a Montana-wide public network. What they have also thrown in is economic development and that kind of thing, and again, [that's] very important. Frank Odaz, the guy who did this, is one of the legends of the network world because of his work in that venue; they've done a terrific job. So the Marino site is a good place to keep track of community networks and also what's going on there. There again, there's a list of them.

We'll go back a little ways. I don't know why I have the Empire State Building Web Cam, because they still have it on April, but allegedly you can see what's going on in Central Park [with that]. Let's look at [Delmarva], a fellow in Maryland [and] Virginia. That's the area down there where, in those three states, the Chesapeake Bay forms the western boundary and the Atlantic Ocean is on the east. As I recall, this particular site, which we're having trouble locating, was put up by the local television station in Salisbury, Maryland. The Delaware Shore is a place where Washington area [people] go to lay in the sun and get sunburned.

It didn't find it, so we're not going to go there... But I wanted to show that because, again, I was trying to show the different entities that take the lead role in doing these things.

We'll try to go to another town. It doesn't look good.

M: [inaudible]

R. Taylor Walsh: Yes, I'll try that. I think we're having some network problems.

There we go. Blacksburg, Virginia is down in the southwestern corner of the state of Virginia, and it is a community network, but it's kind of a special one because when it was founded, Bell Atlantic phone company, which serves the area, was a partner with Virginia Tech down there, and with the city of Blacksburg; and the idea was that the three entities would pool their resources and create this network. Now, initially it was going to be a test bed for high-speed connections, and Bell Atlantic wired a couple of apartment buildings so that you could have access from your apartment building to some high-speed information that was assembled by the university. [They also wanted to] get local merchants involved, and schools, and try to make it more expansive than simply a public enterprise. [They wanted] the entire community.

At that time the connections were only within — it was a proprietary little universe, there was no Internet connectivity, at least until about a year or so ago when everybody said they had to be connected. So they ended up making the connections necessary to get to the Net, and of course they then formed their own Home Page here. As in many cases, everywhere you go where you see a proprietary solution being offered. I mentioned the *Washington Post*, and it uses AT&T's interchange platform, which appeals to the newspaper because the newspaper keeps all the content in its own server. In traditional newspaper mentality you want everything on your own printing press and everything internal; but they've changed running to go out to the Web as well.

So here you see that they've done a very comprehensive job. If you look down this little list of components here, [you can see that] they have contributions pretty much from all corners of that part of the town. Now, Blacksburg is unique because it's so isolated — unlike the Washington, D.C. area which has got 14 counties and three states in it, and millions of people. A lot of people in towns and cities look at this. Alexandria looked at this, then went down there and they decided they wanted to do the same thing.

It's much easier to do this in a self-contained little physical area like Blacksburg than it is in Alexandria where you've got the cable company and Bell Atlantic beating up each other, trying to get the business in town, and then you've got the citizens and the local government, and the *Washington Post*, and America Online — everybody else is going crazy in the D.C. area.

Let's look at the "Village Mall," which is their index to the local businesses. Everybody in Blacksburg has better eyes than I do, apparently. Over time this is what happens, when you see these things just begin to get set up, and over time they become more robust and comprehensive. Again, the beauty of it is that this doesn't pass through one desk or one development industry, but it's like a laundromat.

M: [inaudible]

R. Taylor Walsh: Easy Way Laundromat has got a Home Page? Beam my laundry the easy way, okay. Again, in many cases it's just a text description, and you don't know whether Easy Way knows that this is there, and dialing in from where we are you don't know whether they have approved this or they even know that it's up. Presumably it is, and they've done that.

Okay, here's a store that actually does have a Page. It looks like you can buy stuff, like a consignment store or something. It's done by bnt.com. I always try to go find out who they are, so in other words you've got a wide variety of organizations and services putting organizations and businesses on-line, and somebody acting as a list creator like this. And in this case it's nicely centralized because Blacksburg is so self-contained. Let me do a link over to the *Roanoke Times*. Looks like they want you to subscribe, but they don't want to give you any news.

Another place you can go to find out what's happening in the local market is this *News Link* service, which I need to add to *New Links*. So here somebody has made the effort to be the central repository for all news, associations and organizations on the Web, many of whom are local in nature, particularly newspaper and broadcasting. And I think that we also will see an advertisement down there, so they are doing the old "build-a-list and sell ads," which is a technique for getting business in this crazy thing. So you could replace news with travel, with health, just with whatever it is, and you know that there's going to be a big list out there and there will be ads on it, but it will be a place to go to the sources that you're looking for.

Now, for our purposes, because we're interested in what's happening in local markets that affect businesses, this is an important one because of the role the newspapers have played in business relationships in any particular town. Here's the *Boston Globe*; let's see what they're doing. They've actually got a nice little Page, boston.com, and that football right in there is their dot. Go to "Today's Edition," and we see they've made it nice in black and white like a real newspaper. This is one rendition of how a newspaper sets itself up and how a newspaper involves its readership. Again, this is a piece of this business that obviously is counter-intuitive to a newspaper or a traditional media organization, in which in essence, instead of letters to the editor, becomes letters among the readers, which is oftentimes a major component part of any site.

But the fact that community newspapers are the focal point for many conversations or communities and sub-communities within a metro area — that's what they do, they tell the story of the community. What most of them haven't figured out is how to transfer that role that they've played in yielding the control factor that they've always had — in terms of who gets the story and the column issues dedicated to it, and where it goes in the paper — to providing the space for the community itself to create and write its own news, if you will. In order for them to succeed they have to do that, at least in my view.

So this is a way that the *Globe* has started to try to address that, by involving the readers. Yes?

M: [inaudible]

R. Taylor Walsh: I think this is. It says, "Post your own event."

W: [inaudible]

R. Taylor Walsh: So these are things that users have entered as their favorite thing. Let's see, you put the person's name and address there and it's a way for people to match their interests with one another; presumably that's what they're trying to do. Usually directories have always been staples of any on-line service worth their salt, and the Web has been bereft of them. It's just not part of the Web mentality so far, for providing a way for people to find each other.

M: [inaudible]

R. Taylor Walsh: Yes, yes. I just clicked on "Calendar," and we're getting some stuff. And this is good, they've got a "search" deal. Now, through the calendar thing — and, of course, a newspaper is keeping track with it on a daily basis — let's go over to another entity. We're going to go to Washington and take a look at another entity that lists events and calendar events and things that are happening. This, again, is a Home Page, and you look up at the top and some guy in the military thought this was a good idea to put this Home Page together, so we're going to get a lot of congressional and federal stuff — White House, Congress, everything you want to know about Congress and those guys. There it is.

But down here, I believe, is Washington D.C. locality information, and again here's another place that people have put together stuff relative to the D.C. area.

I was looking for one other thing... You ever look in the personal Home Page registry? I'm not there.

M: [inaudible]

R. Taylor Walsh: Used to call it the phone book, but now it will be the Home Page registry.

W: [inaudible]

R. Taylor Walsh: That does that. What you need to add to that is a matching capability, to show everybody in Washington who likes canoeing how to get in touch with them. That piece isn't there yet. It's simple, it's a fact.

I have been in the on-line business since 1981 myself, and it's been interesting for me to watch the evolution of the Web, because it's a page-based information repository; and what it has not had are the attributes of computer networking that have created electronic communities. They're just not in the Web in its page-based format. Yet images are great and everything, but it hasn't had conferencing affinity for groups, connectivity, newsgroups... It hasn't had directories where you can put out a "show me people who are canoeing in the Washington area." We haven't had that, but you're going to begin to see this.

Netscape just bought this outfit called Collabra, and you'll see other computer conferencing modules begin to come into this market to help overcome this. I think doing this across an interconnected network infrastructure is one of the problems. It's not that easy to do.

The Personal Home Page directory was put together by a guy named Phil. [Here's] "D.C. Power Brokers." We'll go to "Essence." And again, everywhere I've been around the Web there's a Home Page registry beginning to form in metropolitan areas, so the white pages are beginning to form and the yellow pages are beginning to form. It will be interesting to see

how that affects [the business climate] when the phone companies and when Donnelly gets involved.

Okay, so here's a bunch of names of people, and I forget where the heck we are. Here's a whole bunch; presumably these are all voluntarily contributed.

Let's see... What I was looking for was *Washingtonian Magazine*. Remember, we had looked at the Boston calendar of events the *Globe* put together, of course the *Washington Post* does the same thing. And *Washingtonian*, which is where we are right now, although they didn't give us our... But the point I'm trying to get to is that in a WorldWide Web — in the traditional media you've got a variety of different sources pointing to one event; in the Web you can get to the event. How many sources do you need to get the information about one event? And people will come to depend upon a place, a list or a route into any information that they get used to and want to have more information about.

I just wonder what happened to the *Washingtonian's* calendar of events. Maybe people won't go there, or they'll go to the *Washington Post* or some other place. The value of packaging in the editorial world has always been the key to any editorial thrust. They say, "We package, we've got a demographic of users of readers, of subscribers, and we're going to package our editorial to include these pieces because they fit the interests of these people."

I think that's going to break up somewhat. For instance, just in the experience of CapAccess, we became the place where all the local schools, libraries, and local governments put their information. The *Washington Post* comes into the market with *Digital Ink* and goes to all of those guys and says, "You have to give us your stuff and put it on our system." And the local government says, "It's already on CapAccess, go get it there." Well the *Post* says, "No you're obliged to do that, it's public information and you have got to give it to me," and so it will be formatted for their specific system.

And these governments — which are pretty big, a lot bigger than non-profit, and they're strapped for people anyway — they say, "No we're not going to do this, we're going to have one place where you can go, and whoever wants to reproduce it within their site can go get it." So the nature of the relationship and the packaging of content is going to be changed, and that's important because advertising and content are interwoven traditionally in free media or low cost media.

Again, you can tell from all these comments that there's so much that remains to be seen, because a year ago none of these issues were on the table at all, really. So I think they will become more so. That's not limited to the local marketplace, either, by any means. So there's tons of stuff in and around the Washington, D.C. area.

Okay, let me just go over some of these trends in the local markets, some of the factors that are going to influence how all of this has kind of evolved here. Again, these are listed down in the sheets I handed out: things that are happening technically, [things that are happening] within the Web generally, and things that are happening locally in businesses and in communities themselves. These are going to influence and play a role. What kind of role, and the nature and relationships of it, have yet to be determined; but I think the Web in general, and its advancement and its use of *Java* and animation and that kind of thing, is something to think about, particularly if you're in business.

The security and transaction capability is going to be a big issue.

On the content side of the Web we're going to see more personalization, more user involvement in sites and in the nature and the content of the sites themselves. We saw that the *Globe* has made it possible for people to create, to contribute, and to feel part of the site that they are using.

The links — we've seen links all over the place, and the Web also looks like it's going to become part of enterprise-wide, inter-corporate networks. It's going to replace to some extent

or complement the enterprise-wide information systems that we know of today. I think that's one reason Netscape purchased Collabra, because it wants to get into the collaborative work marketplace.

In the PC market, generally people are trading up to the next-generation PCs to get CD capabilities and the operating systems and all this painful stuff, so that we've had that [glued] on to our system over the last year. It will become much simpler, it will be part of the systems themselves and that will make it a lot simpler for just everybody to use, and that means more people will be able to get into this market and be users and be involved.

Locally, the home office and telecommuting are going to become more of a factor. Local businesses are doing business beyond their local markets with greater efficiency. I think we're going to see more private and public sector mingling of project bases.

Another factor is that as corporations are down-sizing, as the government — particularly in the D.C. area, everyone is terrified of the federal down-sizing that is about to take place, because the Washington, D.C. area, as I'm sure you can appreciate, is nothing but federal employees. As that begins to happen everybody is very, very worried, from the individuals themselves to the local economies, the local governments and the tax bases — it's a huge potential problem, and I think, depending on what part of the country you're in, that your city is going to be affected variously by whatever shake-outs there are. So there's a huge [amount of] re-training that needs to take place.

In local media, the newspapers — as we've talked about — their primary objective in all of this has been to protect their classified advertising base, from the business perspective. At least that's been a very important consideration.

There's something called a "New Century Network," which was formed about six months ago by the six leading newspaper companies, media companies for whom newspapering is their primary business — the *Post*, the *New York Times*, the *L.A. Times*, Knight-Ridder — and they got together to try and create some standards for how newspapers get into the business, though all of us think they've already been left behind in that regard. One of the things that they have done is to create a service called careerpath.com, which is a first effort to create a Web site designed for jobs and career information.

I know that everyone has always thought that this was a natural thing to put up into an on-line environment, but my experience is that they've never worked. I don't know why, but they just have never worked. But that's what that group of newspapers is doing. As I said before, many of these newspapers who have been using America Online and CompuServe and Prodigy as their first place to put their stuff on-line are now adding Web pages and Web sites to complement those, so as to not miss the Web train.

And the other factor is that the newspaper industry is suffering layoffs like crazy. Their financing and economics are becoming worse all the time, and the cost of newsprint has gone up a ridiculous amount every year and it has a negative effect on their operations and editorials and news rooms. There's a lot of suffering going on in the news.

The phone companies, locally, really have been interested in competing in the long distance markets and getting in the cable business and being able to deliver video, video-on-demand. The phone companies have spent lots of their money developing the means to get into the video-on-demand market, and have missed the whole Internet thing. Now they're all coming back to it. As I said before, Bell Atlantic is going to roll out an Internet access service.

Other telephone companies in other parts of the country have been variously involved with some kind of Internet access, whether they are Pacific Bell or Ameritech, among others.

[Tape change]

M: Why have the phone companies missed the Internet?

R. Taylor Walsh: Why have the phone companies missed this? I'm only reading tea leaves, but my guess is that they believe that the big win for them is to be in the information business, to be in the entertainment production business, which is why you've seen some of the phone companies in alliance with Hollywood studios and with the big wheels of Hollywood. They want to move film and video into the home and they've seen the cable business selling video productions for years through their channels, and I think they want a piece of that business. Because one of the things that is interesting to me is that the Internet has shown sort of how dirt cheap communications really is. It's like it costs nothing, and it's becoming more and more of a commodity as time goes on. So they want to be getting themselves into the content business.

They never have believed that the personal computer is the device that it is. They've gone through the development of set-top boxes, which are converter boxes which will sit on your TV that will bring whatever you want in at whatever time you want. It's interactive according to those guys in the sense that you can press a button and change the channel; that's interactive to them.

But I think, basically, that it's been a big disbelief in the power of the personal computer, and I've seen the personal computer-based on-line services run through more multimillion dollar business plans in the last 15 years than I care to shake a stick at. Every time somebody has said, "Well the PC won't be used, let's get this special device," the special device hasn't worked because all these guys have underestimated [the PC's] value and power and the appreciation that the individual user has toward what it can do for them. That's my reading of it.

Now, of course, you're hearing a lot about the deployment of ISDN in local markets. ISDN is a digital transport technology, which means it will move computer graphics and files and stuff in a real protected manner, better than your standard phone lines, but it goes across the copper in your house or in your business and you don't have to tear up the floor and put fiber in it. ISDN has been long a part of the telephone company's technical infrastructure for many years; but it has limits in terms of how fast it can transport data. It cannot transport data fast enough to move a movie to your television set.

And if, in fact, the phone companies have been most concerned with delivering video, and that's where their strategy has been — and it's obvious to me that's where it's been — then putting anything into ISDN, which is a relatively slow speed, they have considered not worth their while. Had they jumped on ISDN in the Internet market two years ago there would be no PSI or UUNet; it wouldn't exist today. But they do. So the phone companies, and particularly AT&T and MCI, are getting ready to launch Internet access service, so you ought to be able — if you're not looking at \$10 a month Internet access from these guys in the next six to eight months I'd be surprised — right on your phone bill, another eight to ten bucks for Internet access.

M: [inaudible]

R. Taylor Walsh: Again, this is why you're seeing AT&T — which has this interchange platform, which is a content-based service even though they've set it out as a platform to license to the *Washington Post*, *Minneapolis Times*, *Tribune* and many others — they want to be in the content business. MCI has got a deal with News Corporation, Rupert Murdoch's company; they all want to be in the content business. And this is what the cable guys [are doing]; John Malone is in the

content business. Content is what draws people back, not dial tone. You've got to have [content].

So all across the board you're seeing the communications companies trying to get into the content business. I thought one of the very important recent announcements — if this goes through — was that Time Warner is going to become an Internet access provider to the CompuServe world-wide network. And what this tells me is that Time Warner is looking at this world and saying that it's not good enough for me, Time Warner, because I have to control my points of circulation and where circulation comes from, and the best way to do that is to be an access provider and not depend upon some third party.

It's an interesting thing; they see their electronic printing press then, not just as a bunch of servers over in a site but as a network itself. That's their electronic world-wide network of access, that's their electronic printing press.

So you're seeing the communications and content begin to be fused all along the line of major players.

M: What are your thoughts on what's going to happen with some of these small local providers, access providers with a small Web, trying to divide it? Do you think the big guys will beat out the little guys?

R. Taylor Walsh: Everybody hear the question? Clearly that is the question of the moment, and that is a huge question right now. If I was an economist, a Harvard MBA guy, I would be able to say, "Well, in other industries here's what's happened when the shake-out comes..." And it may or may not apply to this business; this business seems to defy everything that's gone before. But consolidation is clearly going to be in the wind, and I think that the smaller guys are going to say, "We can do a much better job attending to you and your business because we're here in your market, over in Basking Ridge, New Jersey."

And you can say that's what's going to happen, and I presume that these smaller guys are going to try and focus on a niche either within a service area or on some component of Web service of higher value. In the access provider business, where you've got — in the D.C. area we've got 60 access providers and there are probably 60 up here, and they range from everybody who's got 10 lines to the people who've got a T-3. I think something is going to have to happen, some kind of consolidation or some kind of change in business, or Bell Atlantic or New England Bell will buy them out and buy their customers or something. But their economies of scale — they're just re-selling circuits anyway, so for the originator of the circuit that wants to get in the same business his economies are going to let him price the thing much lower than one of these smaller, independent guys.

Now, whether they'll do that or whether we'll see in the access business what's happened in long distance [business], you could have — everybody prices off of AT&T in the long distance service, and you've got hundreds of these little long distance companies out there. It could be the same thing in the network business as well. So I think it's still very much up in the air how that's going to happen, how the financing is going to take place to make that happen.

In local markets we don't want to leave out our friends the cable companies, who look like they want to get into the telephone voice business. They also want to apparently try to roll out access to the Internet through the cable plan. Can you tell us any more about that particular focal point, what the experience has been?

M: [inaudible]

R. Taylor Walsh: Comparative costs between the cable access to the Net versus telephone access?

M: I don't think there's any pricing that has been established, because the trials — correct me if I'm wrong, but most of the trials have been dedicated to deploying cable modems. Zenith and General Instruments, companies that have traditionally made the hardware for the cable industry, have now moved to try to make cable modems.

M: [inaudible]

R. Taylor Walsh: They've been testing connections but not pricing, as far as I'm aware of.

M: [inaudible]

R. Taylor Walsh: It's not only cable modem, but the cable company has got to re-engineer his plant right at what they call the "head end," and they have to build in the Internet technology and structure to back it.

M: [inaudible]

R. Taylor Walsh: But I think it's seen that enough of their problems are solvable, and the ultimate economic model works. And another thing you can look at is companies like Cisco and other companies who make the hardware for the Internet, routers and that kind of thing; they are moving aggressively to develop ISDN modems right now, and presumably other cable-based equipment, so we're just at the beginning of where they've made the commitment. Their business plans now include extending their own lines and products to get to this higher speed infrastructure, whether it's to cable or through ISDN or other telephone company services.

M: [inaudible]

R. Taylor Walsh: You see, a lot of us have been out there and now we're looking at — and here come the train companies, laying their tracks down, and we just hope we're not looked at as buffaloes as they go by.

Elsewhere on the local market are places, particularly in business, and what businesses have to think about — advertising agencies right now are still trying to figure this out, how they play and what they're supposed to do. Their clients are coming to them and saying, "Get me on the Web. What do I do?"

And what I think we're seeing in many cases is that a traditional ad agency is turning to a company locally that is already in the Home Page development business, and doing an alliance with them. For many of these, what I have seen is that they're graphic companies that specialize in high-end graphics, and they do corporate brochures and that kind of thing. High-end visual graphics have, in the last year, extended themselves to actually implement these for CD-ROM or for Home Pages.

And some of them are actually quite good, and they're also building on an existing client base. Down in Washington a group I know has Marriott, USAir, and a whole bunch of other corporate clients for whom they do a wide array of graphics work. And now they're in the Home Page business; they're serving their existing clients.

There's a company out here — I can't recall the name, but they're a provider and they have gone into partnership with another graphic design firm. So you're beginning to see

alliances, and as the specializations get fused, as graphics and networking and other specializations are fused in the Web, you're seeing alliances happen in ad agencies.

I think another thing that you've noticed is that the technology and infrastructure of the Web is basically set. We pretty much know how it works and what's going to make it work. How information and content is displayed is pretty much understood. I mean, there's a lot of work to do, but how pages appear and what you can do in those pages, what you'll be able to do with a *Java*-based or an animation-based [page], that's pretty much understood. We might not be there yet, but the road is there.

From a business perspective and a marketing perspective, what is now just beginning to be applied is a marketing perception and a marketing mentality to this whole thing, and that has been absent. I think right now, around the country and in many cities, the local chapter of the American Marketing Association or somebody like that has been holding seminars, talking about the Internet and the Web as a marketplace because it's now seen that way.

There is a market there; there are millions of people there, and therefore if the customer is there then we have to figure out how to get our clients in front of them. That Zima Home Page I mentioned earlier, those guys at Modem Media in New York have been sort of a leader in this and have done a very good job. But you're beginning to see this — as far as dealing with the Web as a marketplace — where you have marketing principles, and you have to begin to see those things come into play.

Another factor in local areas that relates to the community itself... We talked about the Web technology and business considerations and the media who are central to the business relationships with buyers and sellers. You know, we have something called "regionalism" beginning to emerge in metropolitan areas, and concepts like "fringe cities," where in the Washington [area] — and I guess up here in Boston out on Route 128 or somewhere — there may be a suburb of Boston that's so self-contained that nobody comes to Boston anymore; they work out there and they live in New Hampshire and they come in 20 miles and that's where they work.

The same thing is happening in every metro area around the country. And the public sector is running out of money; what you're seeing is continued spending on technology in the public sector. State and local governments are spending a lot of money on computing, and we see that a lot of states around the country have put in place state-wide information networks linking libraries and schools. It varies from one state to the other how extensive and comprehensive it is, but what they're doing is ultimately creating public points of access to all of the resources on the Web.

Many community networks have worked with libraries to get public access workstations in the libraries and community centers, so you're going to see public access centers linked to the Web. Really, a state-wide network or county-wide network will become much more commonplace in the next couple of years.

Another factor, of course, is the current Congress, which wants to give local control back to states and localities. We have urban cores in the cities that are in big trouble; education is in trouble in many sectors and many parts of the country. Again, though, a lot of schools are getting PCs and getting networks. In our local area I don't think it's possible to speak about metro area webs or a business web in isolation from whatever else is happening; it's just not possible anymore. That's why I bring these factors up, because they'll play a role in how the metro area webs evolve.

We talked about what's happening in Washington. I think that many of the business issues — as you go into a metro area to deal with business and to try and get them on-line and make the sale to them, the issues that they care about are going to be about just generally the same, many times the same that a Reebok or a General Motors or somebody else cares about

in terms of, "What's the value? How do I know this is going to be useful to me, how much is it going to cost me? How am I going to be able to measure the value of this kind of thing?"

So those are the business issues, and again, as I said earlier, I talked about some of the banking and financial relationships and it's too unclear right now to know, for instance, [whether] a small chain of video stores in an area that does business with a bank, a regional bank, is going to be better off working with a large Nations banker or Royal Bank of Canada instead of its traditional local bank it has always done business with. Whether the economics of doing that in the service level is going to be sufficient so that he's going to be compelled to no longer deal with his local regional bank, [it's hard to tell].

[There are a few] other factors I haven't gotten into. Electronic data interchange, electronic commerce, and things that are part of the infrastructure that are going to play a role, but it's still a little early to understand how those are going to play out.

What other questions do you have? Okay, if you didn't [get it] there's a little handout on the chair back there that you can pick up and take with you, and I'll be glad to answer any of your questions, or we can go over any other or visit any other places around the world. Otherwise I thank you for coming.

TUTORIALS DESIGNING AND MAINTAINING YOUR WEB SITE

SPEAKER

Peter Morville

Vice President, Argus Associates, Inc.

Peter Morville: My name is Peter Morville, and I'm Vice President of Argus Associates which is a Web site design consulting firm located in Ann Arbor, Michigan. We work with organizations to help them develop large-scale Web sites. We concentrate on the architecture. When I mention architecture, I refer to things like the organization of information, the labeling of information, cross references between various sections of the Web site, the application of search capabilities, balancing form and functions. We'll talk more about all those in a little while.

In my free time, I'm a manager of on-line services for Michigan ComNet which is an on-line community for non-profit public service agencies in the southeastern Michigan area. In that job, I've come across some of these architectural issues from a little bit of a different perspective, developing an on-line community because a Web site doesn't have to be just a place to disseminate information. It can be a place to bring people together in the community.

I have a background in information and library studies, and for the last few years I've been looking at how we can take some of the skills and the knowledge base from the library community and apply these to the on-line environment. Over several decades there's been a lot of thought put into how we organize print materials, books and encyclopedias and so forth. How do we organize the books themselves? How do we organize collections of books to facilitate browsing and searching? When you walk into a library, you may want to go right to the card catalog or the on-line catalog, do a search and find a particular item. You also might want to browse, look through the shelves, and that introduces the element of serendipity. I might find something I wasn't necessarily looking for, but something that is of interest to me.

Before I move on too far, I'd like to get a little bit of a sense of who are you, what you are looking for. My partner did a similar presentation at Mecklermedia this spring out in San Jose, and he found a lot of the people at that session were in their MIS Departments within their organizations, and they'd been given the job of putting up a Web site for their organization. Their senior management decided that the Internet is a technical medium, computers and networks and so forth, so it makes sense for the MIS Department to do this.

A lot of these folks in the MIS Departments were feeling a little confused, a little concerned. How am I going to do this? Is this something I can do by myself or do I need to bring in other people? Is putting up a Web site simply taking some brochures and sticking them up on-line or is there more to it? So let's take a couple of minutes, and maybe if a few people want to volunteer, just put your hands up and tell us, you know, how is the Web site within your organization being developed? Are you in the MIS Department and has this been dropped in your lap? Do you come from marketing and so forth? Yeah.

M: I am from the MIS Department [inaudible].

Peter Morville: Great. Looks like you are a long way ahead of a lot of other folks. In the front.

M: I was just going to say that I'm a corporate librarian. I'm not from MIS, and the people in the MIS Department feel it's more of an inclination to them because [inaudible] so it's become my task to become the real master and pull all this together.

Peter Morville: Great. Sure, sure.

M: I work in the research division of my organization and the primary reason why we got our license was because he wanted to interact with other research organizations and since we started the whole thing and sort of ended up not [inaudible].

Peter Morville: Okay. We're seeing some difference approaches here. Yeah.

M: [inaudible]

Peter Morville: Great. So we're seeing a few librarians here. In the back there.

M: [inaudible]

Peter Morville: What we're seeing here is sort of a diverse group of people in the audience that have been given or have taken a lead in developing a Web site. We also saw that some Web sites are internal. At this conference and over the past couple of years, it's been much more focused on external Web sites and the marketing component. Over the next few years I think we're going to see much more growth in the idea of an internal Web site as a communication and collaboration tool. Through this presentation, I'm hoping that some of the methodologies that I'm going to talk about for developing a Web site will apply to both internal and external Web sites.

What we're going to talk about today is Web site development, and I'll give a little introduction to that. We're going to talk methodology. There's no one way to develop a Web site, and depending on the size of the organization, the type of your organization and the size of the Web site, there may be many different approaches to take. What we're going to talk about today is mainly focused on a large-scale Web site, a large organization, and we're going to talking about an intra-disciplinary team approach which may involve a number of teams, including an architecture team, which is really my area of expertise. I'm going to focus mostly on that. But also a design team, graphic design and layout, a marketing team: who is your audience and how are you going to reach them? A technical team who is going to make things happen. What can we do with this medium? What are the limitations? What are the opportunities? A project management team who is going to facilitate communication and collaboration between these various teams to make sure that the project stays on time and within the budget.

I'm going to talk about some phases. The research phase is merely an information gathering phase. What are the tools and resources, people and technology that are available to us? How about content? What is the content available that we can put on the Web site?

Then the conceptual design phase: what are we going to do, what's this Web site going to look like? So it's form and function. What's it going to look like, what's it going to do? Planning for production, how is this going to happen? Time lines, opportunities for parallel development, dependencies, a lot of planning here.

Production, making it happen. One of the people that we work with, a technical team, likes to say that production should be painting by number. In the planning for production, you've got everything ironed out and then you just make it happen in production. When in reality, the production phase ends up — you always run into problems and have to put out a lot of fires. Then maintenance, which is a little bit of a wrong label because once your Web site is up — it's been launched, it's up — it's unlikely that you're going to want it to stay just the same as it is. You're going to get feedback from users, suggestions for new content, the technology is

going to evolve, so you're going to be going through a constant process of interactive design, getting feedback and redesign.

That's one of the places where architecture comes in, because you want to make sure that as your site grows you don't have to go back to step one and redesign the whole site. You want to design with growth in mind.

We'll talk a little bit about evaluation. How do you evaluate whether your site is successful, whether it's met its goals? Then just a little bit about keeping current. What are some resources so you can go away from here, after today, and keep up with what is going on?

Before I continue on, if you have questions during this talk, feel free to raise your hand and I'll see if I can take them. If it's something I'm going to cover later then I'll let you know. I'm planning to take a break about halfway through for ten minutes.

What types of organizations develop Web sites? All kinds: business, universities, non-profits, a lot of government agencies, publishers are really starting to explore this medium. Very small companies and very big companies and rich and poor companies.

Probably one of the most popular and often-quoted cartoons is the one with the dogs sitting at the computer and the caption "On the Internet, no one knows you're a Dog." Well, that really hits home, this fact that a small company can really sort of compete in the global marketplace with the larger company in this medium. It's not that easy to tell that the company you're looking at, the Web site you're looking at, comes from a small company. So it has a real leveling affect.

Why do companies put up Web sites? One of the more common reasons is because a competitor put one up, so they know they have to put one up and they're not sure why except that it's the competitor's. The competitor made that decision. The underlying reasons are marketing, putting out those on-line brochures, but you can go beyond that. Sales — there's been a lot of talk at this conference about security and creating a secure environment for financial transactions. I think we can expect that to happen, and sales are going to take off, but they are not necessarily going to be the most important part of the on-line environment.

Information dissemination — a real cheap, fast way to get information out to customers and prospective customers. Customer service, to establish interactivity with your customers, e-mail and Web-based discussion forms are another way to make yourself accessible to your customers and to get feedback.

There's a short term and long term view. Some people put up Web sites with the specific goal in mind of a return on investment, maybe in six months, maybe in a year. Others realize that they're going to have to pour a lot more money into this new environment in order to position themselves strategically to take advantage as the environment grows, as more people come into this environment and as the technologies come into place for secure transactions and so forth.

Under what circumstances? Sometimes a Webmaster gets lots of money and a nice long timeline and kind of goes ahead and develops a Web site in sort of the ideal fashion. More often than not, you get told, "Well, we want a Web site up at the end of next month and we can't really give you any more money, just make it happen." Well, hopefully, this talk will give you a little bit more ammo if you're in that situation to say, "Look, this is important to our organization and it's not simple, it's not throwing some brochures up on-line. Here are some of the things that need to happen. Here are some of the people that need to get involved in order to create a Web site that portrays our company the way we want to be portrayed or represented."

Who develops Web sites? We talked about internal staff and some of you are responsible for developing your Web sites. Some companies hire external consultants and say, "Here's all our content, put a Web site up for us." There are some down sides to that. There's

a lot of potential in involving people within your organization in the development and maintenance of your Web site, but ideally it's an intra-disciplinary team approach. We're going to talk through these teams and these phases, but I do want to make the statement that it is more an art than a science.

This is one way of developing Web sites, and there are probably other ways. Towards the end of the talk, if other people have other ideas we could discuss those as well.

As I mentioned, the marketing team needs to focus on the customer, the audience. Who are we trying to reach? Are there multiple audiences? How are we going to get them to come to our Web site the first time? How are we going to make them come back? They want to do this to a synthesis of conventional market research.

A lot of your organizations are very... you've done plenty of market research, and for instance, throughout this talk I'm going to refer to Argus, my company, which is in collaboration with a number of other companies with complimentary skills. We're at the beginning of developing a large-scale Web site for a company that owns a national chain of bookstores. And I'm going to use that as a sort of case study as we move through this.

Well this national chain of bookstores has done plenty of market research. As they open new bookstores in various cities around the country and they ask questions, you know, what are the demographics of this area and do they match the demographics of the people who tend to frequent our stores? We want to tap into that existing market research, but we also want to realize that now we're opening a bookstore in a new location all together in Cyberspace, the on-line medium. What are the demographics there? Who are our potential customers now? Who are our potential customers in a year, five years from now? How are those two market research studies going to come together?

The marketing team is also responsible for marketing the Web site once it's up. We want to integrate traditional and on-line marketing approaches. Let's make sure that all of our print materials have URLs, bookmarks that are distributed in the stores, our bags, business cards, and so forth. Let's also explore the on-line marketing channels. Is it worth \$40,000 to advertise in *Yahoo* for three months? Is that where our audience is going to be? These are some of the questions the marketing team needs to address.

The architecture team, their responsibility is to create an information architecture that supports [inaudible] navigation. For those people that are browsers, coming in to look around your store, clicking from link to link, you want to make sure they don't get lost, that they have a sense of contact so they move through your site. You also want to allow for people that come into conduct directed searching. I know what book I want. I know the author's name. I just want to find it and order it. Well, I want to allow for that too.

As I mentioned, you also want to create this architecture to allow for a site to grow and expand. We don't want to trap ourselves in an organizational structure that won't allow us to add another menu, that will force us to re-engineer.

So the architecture team is going to go through a process through which they come up with a blueprint that specifies how the information is organized and labeled, the application of search capabilities and the use of navigational aides. We're talking about varying levels of granularity here, from the organization of the whole Web site to the organization of pages and the navigational elements on those pages.

The design team is responsible for coming up with the design philosophy, balancing form and function. You see a lot of splashy graphics out there on Web sites. Is that what we want? Do we want to have almost no graphics and go with functionality so people can come to our site very quickly? Or do we want to find a medium there?

How about designs for multiple platforms and browsers? Something that looks good on *Netscape* with flashy cables and centered tags and so forth, might not look so good to the

America Online or CompuServe user. Do we want to cater to those Netscape browsers and say we're just going to support the 80% of people that are using Netscape? Do we want to stick solely with HTML 2.0 so that everyone has a similar view of the information? Do you want to find a balance somewhere in between? Do we want to split our architecture so we've got a site for Netscape users and a site for text only or for other types of browsers?

These are some of the things that the design team comes up with. Then they actually move forward as we go into production phases in the graphic design. They design the pages, the graphics, the layout of the page, and there's some interchange there between architecture and design. These teams need to work closely together. They're responsible for the copy editing. They may be responsible for the HTML page production. There are also cases where the technical team is going to be responsible for that, but for now we'll just leave it there.

Then there's the technical team that acts in the early phases as a consultant to the other teams. What's possible? What can we do, and what are the implications of these applications? For instance, if I want to put up an on-line conferencing system, a Web-based discussion forum, what are the associated costs? Is that going to have an impact on our timeline? How about maintenance? Do we need conference leaders to keep this conference going? Who is going to do that? The technical team is our reality check in this process.

In the production phase and the maintenance phase, they're the ones that actually build the tools or integrate existing tools. They come up with the processes and the procedures to make sure things happen. They're going to look at what it takes to get this site up, the development cycle. What is it going to take to maintain it and who is going to do that? Are they the same groups of people that develop and implement and maintain the site?

Other tools they might develop or integrate include the search capabilities, on-line databases, a registration and authentication interface. They're going to want to tell you about the implications of that. Will it work on all browsers? Will it cause problems to the users? There we get into some interface design issues and conferencing, as I talked about.

Then we've got that project management team keeping the teams talking and working together, keeping the project within the budget and on time, managing any financial and legal issues that come up, making sure that senior management knows what is happening and relaying any needs of the individual teams to senior management.

They're also looking for areas of overlap between the teams. Sometimes those areas of overlap might be good. You might want to build some redundancies into this project. You also want to look for the gaps. What are we missing? Make sure that those are filled.

In the research and conceptual design phases, there is going to be a lot of collaboration and communication between these teams, a lot of group meetings, brainstorming sessions, meetings of various departments of the organization to make sure that everyone is getting the same picture of what the organization is and where they want to go with this Web site.

So there's a research phase. In this phase we want to think about division of our company and of our Web site and how they relate. The same goes for the mission statement of the company. Let's take a look at that. What are our goals? What are the goals of the Web site? Who is our audience? Do we have more than one? What's the content that's going to be on the site? Who are the contacts in the organization? How are we going to make sure that we get feedback and input from all the people in the organization?

Let's take a look at division. Why is it important? It will be hard to attend this conference and not realize that we're in the midst of a paradigm shift in communication and information sharing. It's on a par with the invention of the printing press and the telephone.

We're at the very beginning of the shift, and the Internet is new and very dynamic. Processing speeds are increasing every year. Bandwidth is moving very quickly. The interface is

improving as money is poured into this arena, and Netscape is going public and the stock is going through the roof. There's a lot of money being poured into designing better interfaces.

With Netscape and *Netscape 2.0* we're seeing an integration into single interface for browsing the Web and doing e-mail and publishing on the Web. People and businesses are becoming much more familiar with this technology, getting past that fear of the technology and starting to push it and say this is what we want to do with it. Now we see where we can go.

So this technology network of information and communications is a snowball that's just started rolling, and I think it's going to pick up speed. We want to think about what this means to your business and your industry. You need to change to survive. There's a few librarians here. In the library field, there's a lot of fear about what this new environment is going to mean to libraries. Some people say that in ten years libraries are going to be gone and it's all going to be on your computer screens. There's quite a lot of librarians out there that don't know if that's true or not. I don't think it is. I think that librarians and information professionals are only going to become more important in this environment.

But for each business, you need to think about the effect now, a year from now, five years from now. How can I leverage this medium? The first step is the marketing, and we've seen that over the past couple of years. We're moving into more sales and on-line transactions. The problems with that factor is that it competes with existing sales channels. Some of the leading companies are moving into the innovation phase. What are some new products and new services that we can create and produce and disseminate that we couldn't before?

One of the companies that we've been working with in Michigan is University Microfilms International. They began as a microfilm company. They print materials, magazines and newspapers, convert them to microfilm and disseminate them to libraries all around the world. In the last several years they've gotten into the CD-ROM business. They said "We're not going to call ourselves University Microfilms anymore because that's an old technology, so we'll just say UMI." They're sticking with that. Now they're thinking, "Are we in the microfilm business or the CD-ROM business? Very recently, due to some internal efforts from some people that have some vision in that company, they're starting to say, "Boy, we've got to look at this Internet. What is that going to do? Is that a way that we can get our information out to people?" Their first idea was, "Let's use it as a marketing tool. Let's just let the world know who we are." And then they thought about sales: "We could sell our microfilm and our CD-ROM products over the Internet."

But now they're starting to push forward and say, "Boy, we don't need microfilm or CD-ROM, at least not in the future. We're going to be able to disseminate our information directly over the Internet. Let's start looking at new products and new ways to package information that we couldn't have done before."

So they're not thinking of themselves as a CD-ROM company or a microfilm company or an Internet company. They're thinking of themselves as being in the information business. You want to think before you start developing your Web site, "Is there something similar going on in my industry?" Along those lines, you want to think about your mission statement. Does it still work? Do I need to re-think my mission statement? How do the goals of my organization and my Web site relate?

Thinking through long-term strategy versus short-term return on investment, "Where do I fit in that picture?" Is this an experiment just to see what happens when I put up a Web site, or is this something that's mission critical that's going to affect whether my business survives or not? All of the answers to these questions are going to affect what kind of budget you want to allocate to your Web project. You can use it for sales or marketing, information dissemination, customer service and so forth.

Are you thinking about your target audience? Are we trying to reach consumers or businesses? It's probably going to be multiple audiences because anyone's going to be able to look at your Web site. How about your business partners? What image do you want to represent to them, or is there information you want to make available to them? How about investors? Do you want to share information with internal staff that's perhaps spread out around the world?

Then we start to get into that line between the external Web and the internal Web. How about journalists? Are we going to use this to spread press releases and background information? Some audience analysis [is needed]. Is your audience using the Web now? Is it going to be using the Web in a few years? What information is most important to them? Why are they going to come to your Web site? Why is the Web a better medium for them to get to your information? So how are they finding information now? Are they making phone calls? Are they getting fax backs? Are they coming into the store?

Okay. So we begin that research phase and we want to start thinking about the content. Yes.

M: I'd like to ask about your audience definition and so forth.

Peter Morville: Sure.

M: One interesting idea, without actually placing the ad, is using an e-mail address or a Web site to see what sort of a response they would get. Do you have any other tools or recommendations on how to evaluate your audience?

Peter Morville: Good question. Let me see if I've got that straight. So you're saying, put up a sort of a temporary Web site with some feedback capability so that people, your audience, might see that and respond and say, "I like the idea of putting up a Web site?"

M: Well the one example I heard talk about was to place ads in the various... You think your audience might be coming from, just to let them know that there is a Web site there to see if anybody gets to it.

Peter Morville: Sure.

M: [inaudible]

Peter Morville: Sure.

M: But I'm wondering if you have any ideas or suggestions.

Peter Morville: A couple off the top of my head. One might be that there's a lot of on-line communities, self-defined communities on the Web, the UseNet group, the listing services. Take a look and see if there are any communities that look like they're composed of people that are your customers and get involved with those communities and see what they're talking about. Maybe throw the question out there. Would a Web site be helpful? What types of things would you like to see on it? So there's one idea.

The other is focus groups, meeting with customers, having them fill out questionnaires or just talking with them about ways in which you can help. Are there other ideas from anyone in the audience?

M: [inaudible]

Peter Morville: Sure. Put up a real basic Web site with a forum, a feedback forum and let your customers tell you, "Yes I'm on the Web, yes I'd like to see information."

Okay. So we're brainstorming through content. What do we have to make available that the customer might want, that these various audiences might want? In a large organization, content is probably going to be spread out across a lot of departments, divisions, subsidiary companies and so forth so you're going to need to identify, "Who do we need to talk to, to see what they would like to make available on the Web." These discussions might need to be facilitated because they might not realize the capabilities, what we can make available. It's not just static information, but we can make dynamic information available. We can make people available on-line, too, so we can assess all of the potential for content.

Then, to borrow from the library field, we want to move toward a collection development policy. Once we've got all of these different pieces of content outlined, we're going to come up with some policy that says what we will and will not include on our Web site. And this might help us down the line as people have suggestions of what to add.

One of the areas where this becomes important is that a lot of Web sites add pointers to other Web sites. Do we want to do that? Do we want to send people away from our Web site? The book store that we're working with, they used to have a Web site that had a sort of virtual library of other bookstores on the Web. Do we want to send people to our competitors? So we want to think through what we do want to include and not include on the Web site.

Then we need to set priorities. We've got our wish list of content, what's realistic. We want to think through the production costs. What is it going to take to make this content available? What is it going to take to maintain it? Are there copyright issues involved? Can we actually legally make this available? You might want to think about the six months and the one year picture. Maybe we'll put this content up now, but we'll look to extend the site over the next several months.

Okay, we've identified who the experts are with respect to content, who are the experts with respect to the audience, your salespeople, the people that are dealing on a daily basis with your audience? Let's bring them into this process and make sure we're getting some input from them.

The same goes with the marketing department. Who are resources for graphic design? Do we have people in-house that can do our graphic design or do we need to go outside for that? What's our technical infrastructure? Do we have an infrastructure to support maintaining information? Do our employees have access to the Web so they can see what is happening and contribute? We need to think through how the teams are going to communicate through the various phases of the project with each other and how they are going to report to senior management. How are we going to solicit input from staff and customers?

So now we're moving into phase two, conceptual design. And this is defining what the Web site will be, the form and the function, developing an architectural blueprint, a design philosophy. We want to come up with templates for the main pages. Those are the most important. Those are the ones people are going to see most often. We want to make sure that we develop pages that don't confuse or frustrate the user but that invite them into your Web site. We're going to come up with templates for subsidiary pages so that as you go into production and you've got lots of content, you can pour that content into these templates to preserve the continuity throughout your Web site and provide users with a sense of context.

If there are advanced tools and features that we want to implement, conferencing and databases and so forth, we want to think through the interface design in this phase. What's the look and feel going to be, how is it going to work? We want to make sure that we're including people in this process. We want to get buy-in. We don't want people upset that they didn't get to tell us their brilliant idea about what to do on the Web site, so we want to be inclusionary.

We talked a little about Web site architecture, organization, labeling, cross-referencing, search and navigation. Why is it important? From the user's perspective, navigation and usability. They need to be able to get around your site. You don't want to frustrate them. You don't want them to get lost. We want to support browsing and searching. From the organization's perspective, you want to support the goals of the marketing team whether it's selling products or simply extending the image of that company. Yes?

M: What kind of person is it that works on the architecture?

Peter Morville: That's a good question. What kind of person is it that works on the architecture? Well from my perspective, it's a librarian or an information professional, somebody that understands how we organize information. Yes?

M: [inaudible]

Peter Morville: Sure. We actually work with a graphic design firm in Ann Arbor and there is a lot of overlap between what we do and what they do. We actually work very well with that firm, but there are other firms that are saying we're going to try to adopt this architecture. We're realizing that it's not just important how people navigate around a page but around a site, so those folks might also take this approach. Yes?

M: [inaudible]

Peter Morville: There's another.

M: [inaudible]

Peter Morville: Great. Yeah?

M: How would you suggest setting up the front page so that people do not get lost?

Peter Morville: That's a good question and we'll get to that and have some slides with some graphics to show. Yeah, one more.

M: [inaudible]

Peter Morville: Right. Great, great. So what we're saying is that there are a lot of traditional disciplines; graphic design, librarianship, interface design, technical communication. A lot of these professions are disciplines that bring things from the traditional environment into the on-line environment. From an organization's perspective, as I mentioned, you want to support the goals of the marketing team and you want to allow for growth. You don't want to have to re-engineer your site because you want to add something.

Okay, well at the very top level of your Web site, you're going to have gateway pages, maybe one page, maybe more. This is the initial point of entry to the Web site. This is the URL

that you publish. There are certain marketing goals that you want to achieve here. You want to have that splash affect — “Wow, this company looks neat.” You also want to have an inviting effect: come further into our Web site and see what we’re about.

They want to serve a shepherding role in redirecting people to certain sections of the site that make sense for them. One of the organizations we’re working with right now is the Library at Michigan. They serve three audiences in order of priority: the Legislature and State Government, Michigan libraries and the citizens of Michigan. They provide various levels of service for those three groups. What we’re doing with them is, they’ve got their gateway page and from that page they can get some basic information about the library. You can also click on an audience specific link. So I can go to the page that’s specifically for the Legislature and State Government or for the libraries or for the citizens.

From there, I’m on my main menu page. The main menu is an information system interface. You’re going to come back to it again and again. It’s the page you’re going to bookmark. It’s the page that you’re going to navigate from. So the focus wants to be on the navigation and the specific use.

A lot of Web sites integrate these two. They try to do everything with one page. They want to put splash and navigation on the same page. In certain cases that’s fine, particularly for small sites, but you want to think about the different things you’re trying to achieve and whether it makes sense to have those be one page or be two or three and so forth.

Okay, with the organization of information, what are some organizational schemes? You’ve got your subject or your topic, the very familiar way to organize information. In the library field we’ve found that’s the primary way people want to search for information: I want to find information on this topic or this subject.

You may organize it by audience, as I mentioned with the Library at Michigan site. There’s the information that is appropriate for each audience.

You may organize it by department. This is often a bad tendency of people putting up Web sites. We think of ourselves as our departments or our divisions. There is marketing and there is sales and there is MIS, so we’ll put up information that way, organized along those lines. The important question to ask is how your audience, your customer, thinks about your information. If so, it makes sense to organize it that way. If not, you want to think about some other schemes.

Some sites might lend themselves to a chronology for at least part of their site, and include timelines: when did things happen. [Or they might arrange by] geography; maps are a very common form of navigation. By product or service, or by format. Do we have a set of images that we want to make available? Do we have software? Do we want to put all of our software in one place?

Then there’s static versus dynamics. Do we have news and information that’s updated everyday and do we want to separate that from other content so that people know where to look for what is new? Or do we want to integrate that at a page level.

We want to explore metaphors. Is there a metaphor that will capture what we’re trying to do? With the chain of bookstores we’re working with, we were thinking you know, okay, we’re going to put up a Web site, what is it going to look like, what are the main menus? We were having some problems, and then we came up with the idea, “Why don’t we think of it as opening a bookstore in cyberspace, on-line? It’s another bookstore, a new bookstore. Let’s try to recreate the environment of coming into a bookstore. What are the options? You might want to go and browse through the stacks. You might want to go and ask a question. Where can I find this book? What hours are you open? So I want to have some human interaction there.

You might even take that a step beyond and say, "I like to go into a bookstore and meet people. Can we build that into this on-line environment?"

[Inaudible] metaphor because there are things we can do here that we can't do in a physical environment. Interactive searching; I want to go into the bookstore and I want to type in the name of the author and the book and I want to find it and order it. In some bookstores they're starting to put in terminals that allow that. We want to do that on our Web site. We might also allow for multiple ways of navigating through the store. You literally can't deal with a physical medium. We can't have our bookstore organized one way and then all of the books organized another way without having two buildings. In the on-line environment that's very easy.

We can also start to customize our bookstore to the individual user. Let's say I have a preferred reader program. Have people type in their likes and dislikes and each time they come back to the store they let us know who they are. Then their screen pops up with the categories of books they're interested in or the music titles they're interested in.

Let's take the shopping cart metaphor or a book bag. Let's say this customer is walking through our bookstore and they've got a shopping cart and they can throw books in as they find ones they're interested in. After half an hour of browsing they pick up four or five books and they come up to the cash register. They say, "Whoa \$400, I can't afford that." And we put these three books back and I'm going to take this book. A month later, one of those books they put back goes on sale, so we send them an e-mail message letting them know that it's available at a lower cost. So as we explore, this metaphor provides some real fuel for brainstorming.

With labeling sort of tied in with organization, we have to have labels for our information before we can organize it. I want to try to use the language of our audience, the terms and phrases they would use. I want to be consistent with the type of language that we're using. You might investigate the use of controlled vocabularies or a thesaurus if you've got a very large Web site or a lot of information to organize, but those tend to scale well. A lot of the terms and phrases are often out of date, so you're very often on your own.

Some ideas for organizing and labeling. Go through the card-sorting exercise where you have an index card for each content item. Then you have various groups of people, maybe your staff, management, your audience take those cards and sort them into piles and label those piles and see what you get. See if you're getting some consistency from person to person as you go through this exercise. You might also do a little competitive analysis. Look what other people are doing on the Web, how they are organizing their information in your area. You can make a lot of good use of whiteboards and brainstorming sessions in this area.

Okay, hierarchical organization. Let's see, why don't we take a ten minute break now before we move ahead on into that, and I'll be up here if anyone wants to come up and just ask any sort of questions.

[Tape change]

Peter Morville: Okay everyone, I want to get started again and sort of move into some more specifics. One of the folks in the audience came up and said they were concerned that I was being a little too general. I hope that in this second section I'm going to get a little more specific with some examples and some of these sort of thoughts and broad issues will start to crystallize in your mind.

Hierarchical organization schemes are a starting place for any Web site. In a hierarchy the information is divided into mutually exclusive subdivisions with classes and sub-classes and a parent/child relationship. It's important to recognize up front that hierarchical organization schemes are a very common and familiar way of organizing information. It's how we do our

organization charts. It's how we classify the animal kingdom. It's how library catalogs are organized.

We're very comfortable with organizing that way and as browsers, we're comfortable with navigating through information that way. There is sort of a built-in sense of context. As we get into talking about hypertext, we realize that while hypertext opens up more opportunities, it also creates new problems.

In your Web site, it's important to try to balance the breadth of your Web site with the depth of your Web site. Here we see an example of something that's broad but shallow, a site that's narrow but deep. Some people on the interface design, the "usability community" has done some studies of hierarchies and have come up with some sort of basic rules. To try to limit the number of choices per menu to eight to twelve, at least at the top level. Try to limit the number of hierarchical levels to three or four. When you start to go beyond these numbers, then the browsing breaks down.

You have to rely on searching. You've seen that with *Yahoo*, if any of you are frequent *Yahoo* users. There are so many menu options, so many hierarchical levels that it's very difficult to browse through and find what you're looking for. You find yourself relying on the search engine.

So many studies have indicated that an hourglass structure works best. Give people eight or so options at the top level, then kind of shrink down three or four options at the subsequent levels. And then you can split off into more options, and if you're talking about perhaps an alphabetical product list, then it's no problem with breaking out into twenty-six options at a deeper level. If you're organizing by topic or subject and it's something that's not as easily segmented, then you again want to keep to eight or twelve options if possible.

M: Excuse me.

Peter Morville: Yes.

M: [inaudible]

Peter Morville: Right. If you've got such a large collection of documents and you realize that browsing is not going to be the central way that people access information, you're going to have to put a lot of effort into the design of your search interface. There may be ways to try to facilitate browsing, but with the amount of information that's on a *Yahoo*, that's very difficult.

M: [inaudible]

Peter Morville: Absolutely. As we'll talk about in a few minutes, you want to make sure that your search option is available on the front page and easily accessible from other pages.

Now, I've got hypertext. One of the most exciting things about the Web is this idea of hypertext, that I can click on a word, I can go to another document which might be on the same computer or might be on a different computer. Also the idea of "hyper-media," because a word can take me to an image or an image can take me to another document, to a video clip and so forth. So we're moving between documents and between media.

Hypertext supports multiple pathways to the same information. There are lots of different ways to get to the same place, but with flexibility and opportunity comes some down sides. It can be very disorienting to the user. So in navigating through hypertext it's very easy to get lost. It's not always easy to get back to where you started. That happens across Web sites

but also within Web sites. How do I get back to the top page? Do I really want to click on the back button ten times?

So this places an added demand on the navigational elements. We want elements that will allow us to get back to the key points in our Web site quickly and easily. We want to have a sense of context, to understand where I am in the Web site. So hypertext can be used to compliment the hierarchical organization structure, but you want to make sure that you don't get people lost. Yes?

M: [inaudible]

Peter Morville: Okay. Should we use page numbers and should we tell people how many pages are in your Web site? Page numbers are really going to be most applicable if you are talking about a linear document. Most Web sites are not linear documents. We're going to come into a Web site and there are multiple paths that I can go down. I can choose my own way of navigating, but there may be linear documents within my Web site. I've got my product catalog up there. That might be something that I navigate in a linear fashion. In that case, I do want page numbers and I want the ability to go to the next page and the previous page. I've got a diagram coming up that will show that. Yes?

M: How about the use of an index of the whole site and have that as a selection?

Peter Morville: The idea of an index to the whole site is a great one. It actually sort of refers to the second question, "Do I want how many pages on this Web site?" You want to give people a feel for the size of the Web site. Is this a *Yahoo* or is it five or ten pages that I can get around pretty quickly? So you might want to have a map to your Web site that shows all different locations and where they are. That might be represented graphically with some sort of map or text with some instructions and some description of the various sections of the site.

So here I see a representation on hierarchy and hypertext. Someone can come in at the top level. Yes?

M: [inaudible]

Peter Morville: That's a good question. The content, the organization of information at the user level is also a back-end component. How do we organize the information at the back-end? In that organization it may reflect the organization at the front-end or it may organize information quite differently. You might have all of our documents in one directory. You might have all of our graphics in another directory.

You want to think through that back-end architecture just like we think through the front-end but with different goals in mind. We want to make sure that people who are maintaining the Web site can find a particular document. You want to make sure it's labeled, not as X12.HTML, but as something they can easily find and reference. You might have a table, a relational table or database so that I can type in a key word of the document and I can find where that document is and go in and edit it. I'll talk a little bit more about maintenance, and we might come back to this issue a little later on.

So we come into the structure and we can come through hierarchically but there are also other ways to get to certain sections. We might thwart that hyperlink and click up to that document. That's where you've got to make sure that there's some sense of context. How are people going to know where they are in your Web site when they've clicked on a hyper-link?

The navigational elements are part of the architecture, but they're implemented at the page level and they do have site-wide implications. The goals are to provide that sense of context and consistency, to facilitate browsing and search, and to balance the ability to get anywhere from anywhere with the avoidance of clutter. We don't want a link to every single page of our Web site on every single page. How do we balance those?

We want to take advantage of the consistent use of landmarks. Elements on a page should be organized on each page in a consistent place. We want links to the gateway page, to the main menu, to an index, to various sections, linked to the searching page. This navigation can be done through hypertext links, this text tool. You can use arrows, we can use maps, we can use icons. We'll take a look at a study of some icons in a little while.

Okay, elements on a page. You're going to have a document header, you're going to have a navigation bar, the body of the document. Depending on the length of the page, we may want another navigation bar. Then we want a mega-information area, information about the page and about the site. Somebody prints out your Home Page and takes it in for a presentation. Are people going to be able to find your Web site later on that day? Are they going to know who you are? Are they going to be able to contact you and ask you for more information?

The document header can be used to provide contextual clues through the use of text or graphics. On every page of your Web site, I want to know that I'm in your Web site. What is the organization that is sponsoring this Web site?

Let's borrow some of the graphic elements from the main page and take them onto the subsidiary pages so that we've got that consistency. Maybe textual clues. Let's include the title of your Web site somewhere. Let's have some links showing the position in the hierarchy.

Let me actually switch over here. An example of that is on an information service that we co-sponsor with the University of Michigan, the clearinghouse for subject-oriented Internet resource guides. You see that on the main page we've got that header. As we select the Arts and Entertainment page, then we've got a link that says "clearinghouse" and then Arts and Entertainment so it gives you a sense of the level you're at. If you select a particular guide within the clearinghouse, that text, Arts and Entertainment, becomes a link, a navigational element so we can connect back to the arts and entertainment section. We know we're in a guide that's part of that section. You can also link right back to the top level of the clearinghouse.

Through the use of common elements from the gateway page, the use of size and color schemes — and let me actually switch back there for a second. On the main page, we've got a larger, more prominent graphic. As we move to the subsidiary page we shrink the graphic size to give you the sense that this is not the main page, this is a secondary page but we borrowed the color scheme and the name from the front page to show you you're still in that Web site.

Okay, we want to have a navigation bar. It might be integrated into the header, part of that header graphic. Perhaps your header is a link back to your Home Page, your main menu. You might want to include this navigation bar at the top and at the bottom. When people are reading through long documents they don't want to have to scroll up to the top in order to get back to the main page.

One of the links that you might want to have is certainly the main menu. You should always be able to get back to the main menu. Maybe a link back to the top of the product section or the services section. You want to have a link on each page that takes us to contact information or maybe ordering information.

There is this idea of specific links where we're pointing to those specific sections or we might want to make use of a general navigational bar. Let's take a look at that. Here's an example. As we're moving through this Web site, let's say we're on page two. Where might we

want to go? We might want to move linearly and go to the previous page, page one. We might want to go to the next page, page three. Or we might want to move up a section to products, move up a hierarchical level. So we can do that with the back and forward and up arrows. One second. We've got the length of the main menu and we've got the link to our search engine. This is just an example. You want to go through this sort of process of thinking at each point in the Web site. Where do people want to go and how can we represent those options through navigation? Yeah?

M: [inaudible]

Peter Morville: That's a good question. Don't the back and forward arrows repeat what's on the browser? Well not necessarily. But it can be a point of confusion.

On your browser you've got those back and forward arrows and what those do is, you click on back and it will take you to the last page you were on. You click on forward and it will take you to the last page you were on if you just went back. It's easy to get lost using these back and forwards. They don't necessarily correlate with what we've got here because in this case the back and forward arrows refer to linear movement through a document.

So we've got the product catalog and the next page takes us to the next page in the catalog. That would not be the same as the forward link on the browser. The back link will take us to the previous page of the catalog. That may or may not correlate with the browser's buttons. But you do raise a good point because there's potential confusion there for the user because they're used to using those arrow keys on the browser and now I've got some new arrow keys. We need to think through, is this going to work? Is there some way we can explain these arrows? Shall we have textural clues like next page and previous page? Or should we stick with those links to specific sections and avoid that potential confusion? Yeah?

M: [inaudible]

Peter Morville: Sure. Okay. You raise an interface design question there. Do we want to have our entire product catalog in one Web page?

M: [inaudible]

Peter Morville: There again, it would be parts of the Web site that you do not go through in this linear way if you've got a particular product. Here we've got product one, two and three. Those might all be one page for product one, for product two and for product three and you can scroll down through those pages. Let's say we've gone to the annual report. That's a large document, but you do want to navigate through linearly. I want to read the annual report page by page. Most likely we're going to want to split those pages up so that a user doesn't scroll through one long page but can go from page to page. Then we want to think about how we allow them to navigate, like flipping the pages of a book. In the back, yeah?

M: [inaudible]

Peter Morville: Good question there as well, and I'm glad that we're getting a lot of questions because this is not an easy issue at all and this bar may or may not make sense. The question is, if you click on that up arrow, let's say when you're on page two, where is that going to take you? Could you have gotten to page two from different locations? Very possibly. That might be a good case against using this type of navigation system. Yes?

M: [inaudible]

Peter Morville: That's a good point. With that annual report, do we want to have a table of contents? People might want to go through linearly, but they also might want to jump right to the financials. Let's provide that capability and also the ability to go back to the table of contents. Yeah, in the front?

M: [inaudible]

Peter Morville: Great point. With *Netscape 2.0* there's a couple of new tools that we can utilize for navigational purposes. One is the scrolling menu that we can have available on every page, so you've always got the same options available on each page. Now there is the ledge or the bar that might be used for corporate advertisement but also might be used for navigational tools. So we can have the same bar available on each page. Yes?

M: [inaudible]

Peter Morville: To my knowledge, no other browsers can do that right now. Each came out, *Netscape 2.0* does have that idea of a ledge or a banner built into the proposal specs, so we might expect to see that sometime in the near future.

M: [inaudible]

Peter Morville: Okay. There are some other browsers and we're thinking about that capability. Those are the things we want to keep in mind because the technology is going to continue to evolve, the tools are going to get better and we're going to have other ways of tackling this navigational problem.

When you're doing architecture you also want to involve the marketing team because there's some interplay there. Do we want to have an advertisement as part of our page and if so, let's set it up ahead of time with that in mind. Let's reserve a space for the ad and not stick it in after the fact.

At the broader level, marketing might play into the structure of the Web site itself. It's the idea of billboards. We talked about that dual use of main menus, the flash for sort of keeping things up-to-date, but also as a navigational system. One idea is to split off the marketing and the flash and the up-to-date aspects into billboards.

Let's say our bookstore has a marketing campaign around Colin Powell's new book. Let's create a billboard for that, a sort of Web site or Web page that's not part of our structure and that can come and go with our marketing campaign.

Let's build some flash into that. Let's have some fancy graphics. Let's have a link directly to ordering your copy of Colin Powell's book and also maybe to the main menu. If we've got those types of links coming into a sort of sub-level of the main page of the main site, going into Colin Powell's order screen you want to make sure that the users understand that they're part of this large site and understand how to get back to that main menu.

Let's just take a few minutes now and look at a case study. Let's look at Netscape's page, which is probably familiar to quite a few of you. Let's just critically analyze it and see what they're doing with architecture and navigation.

We're not going to be able to see the whole page on here. That's another sort of navigation issue. Can we see the whole page? Towards the back of your handout I've printed

out that page, so if you want to get a broader look at what we're dealing with you can look on your handout.

What we've got at the very top of this page, you see the Netscape emblem, the "N" coming across the globe and "Welcome to Netscape" inviting us in. There's a number of icons and we're going to talk a little more about icons in a little while. But icons are pictures trying to represent what's within each of these categories. We've got a clickable menu at the top: Exploring the Net, Company and Products, Netscape Store, User Reference, Assistance and Community. As we go down the page, we see that integration of marketing. We've got Netscape downloaded.

We've also got some dynamic information on this page, some press releases, more marketing. Press now to download version 2.0. We've got some navigational menus: Exploring the Net, Netscape Store, Community. One of the things I find confusing about this site is that these menus don't correspond exactly with the menus at the top of the screen, with those icons. That loses me a little bit. What are all of the options for places to go on this Web site? I'd actually have to go through and check off all the different areas and see where the overlap is.

At the bottom they've got a navigational bar. It's nice that they've got that bar there. It's got pointers to some of the major parts of the site, but again it doesn't correspond exactly with these other menus. So I'm a little confused about what all the options are, but I've also got some navigational tools that are there.

I select one of these options; let's select Community. It's got the same Netscape emblem at the top giving us a sense of continuity. Everyone knows what that big "N" is. We've also got an extension of the icon now from the smaller penguin's icon. We've got the larger thing, so it gives us that sense of continuity. We know where we are. Then we've got some content, some marketing, some more navigation. Then we've got that same navigational bar that we had on the front page. So it gives us some consistency and some sense of context. Also notice the information on the bottom telling us that this is Netscape and giving us an e-mail address and a phone number to call for more information.

Does anyone have any comments or questions about the Netscape site? Okay.

Let's talk a little bit about searching the Web site. We want to provide a search interface if our site is larger than ten or so pages. We want to start thinking about applying searching as an alternate means of navigation. What are the things that we can use to allow people to search? There are menu and document titles. Those are very often the best sort of content words, the best key words to search on because we've put a lot of time into labeling each document and labeling each menu. Let's take advantage of that rich vocabulary. Let's use that for searching. But other options: you can full text index the whole Web site, every document people can search. That's easier from the publishers point of view because you can run a full text index across all of your information and update it as you need to. It's not so easy from the user's prospective. It puts a high demand on their ability to use search techniques. We've got a question. Yes?

[Tape change]

Peter Morville: What she's asking is if a certain word or phrase appears several or dozens of times in your Web site and someone searches on that, then they're going to pull up all of those hits and it's going to be frustrating for them to look through. Well, part of that is a labeling issue. When we're labeling documents and titles and so forth, we want to think through the fact that these are going to be searched. We want to come up with unique names, and so a document might say Colin Powell but it also might have something like biography, Colin

Powell's contact information or whatever. So we're adding some clues that will facilitate searching. Yeah?

M: [inaudible]

Peter Morville: Well what I'm talking about here is once we've got that table of contents and it's a very large one, we can index all of the terms within that and provide things like searching on that index. Yes?

M: Isn't part of that problem going to be taken away by searching that you use, in other words [inaudible].

Peter Morville: Okay. You bring up the issue of when other people are going to search your Web site. Let me hold out for a second. The options for you as a publisher of information...what I'm talking about here is, you're providing a search capability as part of your site. You're purchasing a commercial search engine or taking advantage of some shareware. You're controlling how people are going to search your Web site. The options are menu and document titles, full text, and you might take it a step further and develop your own database. Each document might have an author name or key words or a date. You can go that step further and provide some real flexible and powerful searching on your Web site. Yes?

M: I think the issue of one of the earlier questions was getting at it if you've got one document, one page that's about Colin Powell, but you've got eight or nine references across your menus or other reference points on your Web site. If you're searching through those menus you're going to have seven or eight occurrences referring to the same document.

Peter Morville: Sure.

M: We're struggling with this, too, because we're going to have [inaudible] and I was wondering if there's a way that if we sat down at the table and listed every document once that we could search the table of contents and that way we don't give somebody who is searching eight instances of the same thing.

Peter Morville: Right. Thank you for that. That clarifies this issue. If you've got multiple references to Colin Powell but they're all pointing to the same document and you do a search on menu and document titles, you're going to bring up all those references. That's a decision you can make. You can say, "We're only going to provide searching on document titles, or "I'm going to give people the ability to choose whether they search menu or document titles." Or "I'm going to come up with a secondary index that removes all of the multiple references to documents."

There's a lot of flexibility in here.

M: [inaudible]

Peter Morville: Sure. What you're going to find, particularly in the commercial search engines, is a lot of flexibility. The ability to create stop words, words that appear so often that you don't want to even use them for searching. The ability to remove duplicates. So we can do that. What we want to think about is what is the content that we've got, how do we want to do searching?

Then we can make sure that we purchase the right search engine that will accommodate that. Yeah?

M: Is there a list of all the search engines and what the different features are?

Peter Morville: Probably. There's a list of everything. Yes. I would go to *Yahoo* and I would search for search engines or commercial search engines or search tools. I'm positive they've actually got a directory of all the different commercial search tools. It can be pretty confusing to look through and pick out which ones you want because there's all kinds of different features and so forth. That's nothing we can really go into here. But there is a lot of flexibility. You don't want to think too narrowly about what you can do with searching.

You want to put plenty of thought into your interface design. Far too often you get to a Web site and you don't really know what you're searching. Are you searching those document titles, are you searching the full text? Tell the user what they're searching and provide a clear explanation of how it can be searched. Do we have [inaudible] capabilities? Can we use "ands" and "ors" and "nots?" Can we use proximity and adjacent searching? This word has to be near to this word, this word has to immediately follow that word. Are searches case sensitive? Can we use nesting to get really complex searches going? Is there relevance ranking? You mentioned [inaudible] which takes advantage of relevance ranking, so it does a full-text search on the documents and then it provides the hits that it thinks are most relevant to you based on where the terms appeared in the document, whether they were in the title or further down in the body, how often those words appeared.

Other engines are more bullion-oriented and they will give you the hits, only the hits that matched your criterion to tell the user which type of search engine they're using.

You want to have an explicit relationship between browsing and searching, if possible. If people can browse through those menu and document titles and they know they can search those menu and document titles, it's going to give them some clues to the language that you're using and the language that they might use in doing a search.

You want to know how important searching will be on your site. Should you have a novice and an expert option? Are there going to be people that come in and just want to type a word and find something but also people that want to come in and do a very complex query? There's a lot of thought that can go into query interfaces and you want to know how important it is. Let's make sure it's usable.

I'm not going to go into detail on advanced tool design, but it's something you want to think through in the conceptual design phase. If we're going to add registration authentication, what is the interface? Is the first page that people come into a registration screen? Can they get beyond that without registering? Is authentication going to get in the way each time they come to the Web site? Do they need to type their log-in and password each time? Or is there some way to incorporate that with their hot links so they can always get back to your page?

The same thing with on-line databases and conferencing and on-line forums. You want to consider interface design issues, and people from the technical communications fields, interface design and usability and so forth, graphic designers to help with these. Yes?

M: [inaudible]

Peter Morville: Again, I'm sure that there is and *Yahoo* will be the first place to look. Search for conferencing and forums and I'm sure you'll find a directory that addresses some of those.

Okay, we want to put our Web site through some usability testing, some prototyping. Let's create those main pages, let's set up the templates for some subsidiary pages and let's test

in on some of our intended audiences. One way to test it might be to have people sit down at a computer with your prototype and have them talk out loud as they try to navigate through your Web site. "Okay, I'm trying to find your products. I'm clicking on this menu. I'm lost now." Capture that on tape and analyze where are people getting lost, what things are working and what aren't.

Let's make sure that they're trying some different types of searching. Let's have some people just casually browsing your site and let's give some people some directed searches to make sure that we're supporting both. Then let's go to the redesign.

With usability in mind, we're going to switch over to another case study. Sun Microsystems put a lot of time and effort into designing their internal Web site. They've got some experts there in user interface design that were involved in this process. We're going to take a look at their use of icons and just talk a little bit about how those work, but the URLs on your handout, I'd invite you to take a look at that URL sometime later and read through their paper on how they designed their Web site. It's very interesting.

While that's loading, I'll just point out that they've got their bar on top there, a couple of navigational elements, icons. One looks like a house, probably to the Home Page. Another with a magnifying glass, I guess a search, linking to the search interface. Are those easy to understand? Relatively so. You need to think it through, and we're going to take a look at how they went through coming up with some of these icons.

Here are some examples. We see at the top, these are actually their final product, their final icons after they'd been through several iterations. They developed an icon and then had people look at their image and say what came to mind to determine whether it was in sync with the intended meaning.

At the top here we've got a picture of the earth and the intended meaning. Here is a geographic view of the company and the fact that there are branch offices in different locations. Clicking on that would take us to the branch offices. The users interpretations were things like: it's a world, it's a global view, it's a planet. So we're in the same ballpark there. With the benefits package being the intended medium, interpretations were help field, money, health care is expensive, Clinton's health care plan, hospital, don't know, benefits.

We're getting sort of a wider range of thoughts here. It's not clear to all of the users what happens when they click on that icon. For the television set, which is meant to represent public relations, everyone just said TV. They took the physical representation for what it was. They tried to represent the product catalog with a computer and a CD-ROM. People said systems-oriented, disk, CD, computer CD, CD-ROM. So people are sort of taking a literal interpretation.

With this tool box, specialized tools, people thought it was a briefcase, linked to personal information, a toolbox and a briefcase again.

Let's just take one more here. I've got this bulletin board. It's a "What's New" bulletin board. That's what it's meant to convey. Most of them said it's a bulletin board. One person said it's the laundry. So what we're seeing here with icons is that even when you put them through a lot of testing and iteration and redesign, you still have differing opinions of what they might link you to.

You can take your own lesson from that. The lesson that I took is, I found it to be useful, but not necessarily the first time you come to the Web site. The first time I come to their Web site and I see that bulletin board, if I'm the person that thinks it's laundry it can be pretty misleading for me. But if that's complemented with some text that tells me that this is a bulletin board, the next time I come back to that Web site, hopefully I've associated that picture with a bulletin board and I don't even take the time to read the text. That's the thinking

behind icons. So I can't tell you whether you should or shouldn't use icons, but there are plenty of problems involved and people have comments about that.

M: What if you use the icons on the first page with the text and then on subsequent pages you just have the icons?

Peter Morville: Sure. Once you've sort of built in that connection between the icon and what you're trying to convey, then you might take advantage of those icons on subsequent pages without the text. You want to go through some testing to make sure that it does click in people's minds soon enough. Yeah.

M: [inaudible]

Peter Morville: Right. People might connect right directly to that page and skip through the part where it tells you what the icon means. Yes?

M: How about something on there that's very obvious? I think one icon that seems to be the common universal is a question mark for help.

Peter Morville: Right.

M: Having a help screen, which then does explain the icons.

Peter Morville: Right.

M: So they can always click that.

Peter Morville: Right. Coming up with a Help button using the question mark, which is a pretty common use, clicking to describe the icons. Yeah?

M: [inaudible]

Peter Morville: Right. A suggestion to have text alternatives so you don't have to rely on the icons. Another thing that icons introduce is sort of growth or extension issues. It might come upon your top page with five icons that all really make sense and work. Then six months later you say I want to add another category and I can't think of an icon. Well what do you do then? So you want to think to that idea of growth, too.

Moving into the planning for production phase, how will the Web site be implemented? We want to go through some needs analysis and some resource identification. What do we have at our disposal already in terms of people and technology and content and so forth? What do we need that we don't have?

The technical and architecture teams want to think through that information ownership blueprint. Who has the content now? What format is it in? Are the same people that own and create the information going to be the people that manage the information on-line? Process ownership; how is it going to get from that original state into the Web site? Are we going to have a centralized or decentralized model? Should it all go to a Webmaster? Just send all of your print documents to the Webmaster and they'll put in on-line. Or do we want to have the people that are creating the content publish it on the Web at the same time? We want to

rethink the way that we're creating content in the first place so that it fits in with this new medium.

How much information do we already have in digital format for the information that's in print form? What is the cost of conversion versus data entry, optical scanning and so forth? Do we want to do it in-house or do we want an outsource? Do we want to train people in our organization to do HTML? Do we want to create an interface for them to enter content without having to know HTML, taking advantage of those templates? Or is it better just to outsource it, maybe in the development phase to outsource it and in the maintenance phase we start to have people coming up to speed.

Throughout all of this is project management, the planning through production that's really important. We want to think through the dependencies and the opportunities for parallel processes. Can we have the technical team making the server ready and implementing some of those advance tools while the design team is designing the graphics and doing the page layout?

We want to make sure that we're on time and keeping within the budget. So we move into production, as I mentioned. Ideally it's painting by number, but in reality it's crisis management. We thought it was going to work this way, but all of a sudden we've found out that the conversion isn't working properly, we can't really get our hands on this content. We found out it's copyrighted by someone else. So we're working out all of the real issues and making things happen and working through those parallel processes.

What are the things that we can be doing that we want to have done when the Web site it up? Should we start training staff now? Who is going to have to know what? Do we need to create documentation so that we can manage this information over time?

We can start data testing. First, let's have the teams run through our prototypes and make sure things are working. Then let's start getting some of the customers in, seeing what is happening and redesigning based on the feedback.

At some point we're going to want to launch our Web site, but we don't want to do it too early. There's a lot of Web sites out there with construction signs or empty menus. On the Web, just like everywhere else, you only get that first chance to make a first impression. When I go to a Web site and see a bunch of construction signs and there's nothing interesting, it's going to take a lot to get me back there again. So you want to be careful not to launch too early, but you've got to balance that with the demand to show that you're moving in this direction. And you want to make sure that — yes?

M: [inaudible]

Peter Morville: How often do you launch different versions? Well, the way that I'm using the term launch is sort of from the very beginning saying if the organization doesn't have a Web site, there's going to be that time when you launch it. You want to make sure that you've got enough there and that it's well designed and that you don't have a lot of empty back alleys before you launch. But then this is where marketing ties in. Are we going to have product launches in our Web site? Are we going to have another marketing effort every six months? Are we going to publicize on the Web and in our print literature? We want to make sure that we take advantage of integrating the traditional and the new marketing tools. Yes?

M: Another issue that comes to mind is how often you refresh and revitalize the content that's there. If you just put up a Web service and it stays stagnant for three or six months, nobody is going to come visit you.

Peter Morville: Right.

M: People will...you want it to have something dynamic that causes your customer base or the audience you to serve come back to you every week or every two weeks, in some places everyday.

Peter Morville: All right. You make a good point that you want to make sure that your site has some dynamic component, that there's a reason for people to come back. You want to make sure that the procedures for maintaining the currency of your information are in place before you launch so that you're not going to launch and then spend six months figuring out how you're going to keep that "what's new this week" section up-to-date. These are things you want to think through before you launch.

With marketing, take advantage of traditional channels: press releases, advertising, print literature, business cards and so forth. But think about how you can also leverage some of the marketing tools on the Web. Let's make sure that we post to all of the directories, the *Yahoos*, the "I"-Nets, open markets and directories of commercial services.

There are some Web sites that brought a lot of these directories together. There's one page to post to everywhere; I can't remember it offhand but *Yahoo* is probably a good place to look for it. How about discussion groups? Are there communities of people that might be interested in your products?

Here you've got to think real carefully about Medi-Cal. Am I going to get flamed if I post to this community? Or maybe do I have some interesting content, a value-added service that I can relay to these communities. I'm providing a valuable service to you, here this is the URL, but they're going to link back to your Web site as well. So are there ways to leverage these on-line communities?

And then on-line advertising. It's really just taken off this year with *Yahoo* and *Pathfinder* and *GNN* and so forth. I think the attraction there is that the people who are seeing those ads are already on-line, they're already on the Web and you can have a direct link from *Yahoo* to your Web site. So there's a smoother connection between reading the ad and connecting to your Web site. You want to think through the costs of that as well. Yes?

M: [inaudible]

Peter Morville: That's a tough question about time frame, and another one that is similar is cost. Someone asked me during the break. It can just be all over the board. From getting our Web site up in three months, a large-scale Web site, it's hard to picture doing that in less than three months, although probably some of you have done it.

But let's take three months as being the short timescale. It's enough time to get these teams together and move through these phases. It's a pretty frantic pace, but it can be done. On the longest scale, six months to a year. It's hard to see going that long. It seems like you're dragging things out. So maybe three to six months is a good range for taking your first attempt at doing it in a way that represents your organization well. With costs all over the spectrum from a couple of hundred dollars to have a college student put your Web page up to five to ten thousand to put up a real basic site that's done professionally to several million dollars for a Web site. There are Web sites that people have put several million dollars into.

M: What would be an example of a several million dollar Web site?

Peter Morville: Probably *Pathfinder*, although I don't know that for sure. There's an organization in the Boston area that's putting up *Barrons Financial Magazine On-line* and that's in the several

millions of dollars. They tie in a lot of back-end information so that as you read through the magazine you have access to lots of sources of historical financial information, but that's an example.

Okay, with maintenance you want to keep your content fresh and up-to-date. If you designed it separating the static from the dynamic information, users know where to come to look for the newest most up-to-date information.

As I mentioned earlier, maintenance is a little bit of a misnomer because the site is going to grow and evolve over time. You want to respond to user feedback. People are finding it hard to find this particular type of information that's important to them so you want to redesign based on that. You want to grow. It's going to be more information over time that you might want to make available. The first iteration of our Web site might only be the beginning. Hopefully we've designed the architecture so it will scale up, but in some cases that's impossible.

We want to evaluate success. What are our metrics of success? That depends on our goals in the beginning, what we hope to achieve. Were we trying to get a return on our investment? Were we trying to do sales, or was this more of an image thing?

Some tools for evaluation: the most basic ones are the standard usage logs that tell you the host computer that the people came from and that sometimes gives you an indication of who is looking, if it came from a commercial or a government or an educational or a non-profit site, and if it came from the U.S. or Canada or Japan or Sweden.

If you want to go beyond that, try assessing the demographics of people that are coming into our Web site and find some way of surveying the audience. That's when the registration and authentication comes in. It imposes something of a barrier to access. It might reduce the numbers of people using your site and cause some frustration, but it also allows you to tap into who is coming to the Web site and what they earn and what company they are from, the demographics. How often are they visiting, how long are they staying? If you've got content that's attractive enough that people want to get it, they'll go through that extra step. But if you don't, you've got to be real careful.

You might try contests and so forth to draw them in — every hundredth user wins a prize or something like that. People in marketing departments have found all sorts of ways to find out who is using their print products and how successful they're being. You just want to take some of those and see if they apply to the on-line medium.

So we've got lead tracking — how many people have come into the Web site, who are they and what is the result. Are they making follow-up calls, are they asking for our product catalogs, are they actually buying our products? There are no quick or easy ways to do this, but there are ways to make it happen and those are really not any different from the traditional sort of marketing world. From your Web site you've got a phone number with an extension that's unique to that Web site, so you know that a phone call came from the Web site and so forth.

So just to review, we talked about this intra-disciplinary team approach with the architecture and design and marketing and technical and project management teams all working together. From working through these phases, from research to conceptual design, planning for production, to production, to maintenance, and redesign and growth and so forth.

We've talked a little bit about evaluation, the different ways to look at this. First of all, a lot of the ideas behind design are not going to change. Coming out of those technical communication and interface design fields, there are a lot of rules and ways that we know to organize information to make it usable. But the technology is going to keep changing. Today it's HTML, but now we're seeing *Java* and *VRML*, and Microsoft has a technology called *Blackbird*

that's sort of like HTML but very different and might compete with HTML and might replace HTML or might never really take off. We'll have to see.

You need to keep up with the technologies and understand what we can do and then we want to make sure that what we do makes sense from a design and an architecture point of view as well as marketing.

At the back of your handout there are some Web design resources, things that I found interesting or instructive about this topic. I'd just like to point out one of them that I would really encourage you to take a look at and that's the *Word-Wide Web Style Manual* from Yale. It's very interesting to read through and it covers a lot of the topics that we've covered today.

So you want to keep up-to-date, take a look at some of these resources and you might want to hire a consultant. I'm happy to talk with anyone afterwards about that option.

Just as I brought up that consultant idea, you might want to do some of this in-house and you might want to do some of it externally. You want to look at what you have in-house and then think about what you need to bring in, who you need to bring in to make this happen. You might have technical communications people and interface design people already in house and you might need to bring someone in with a technical background or vice versa.

So these teams that I talked about might be part of those teams might be internal and part of them might be external.

That's all I have for today, but I'd be happy to take questions for awhile up here and then afterwards by the site. Any questions right now?

M: Yeah. Let me ask you a real basic question.

Peter Morville: Sure.

M: I'm putting together a whole shopping list of the components that I would require on a Web site internal to the corporation and internal to my own mainframe design. Of course you need a Web server, a software environment, you need a search implement of some sort and I think you need some programming interface languages like [inaudible].

Peter Morville: I've got a comment to make and then we'll see if there's any other suggestions from people. When you're going about developing a site for your organization, you don't have to go with an internal Web server. You don't have to buy a Sun workstation and hire someone to manage it and get your T-I connection. There are options from Internet service providers to get what is called "virtual host service." Essentially you can lease space on a machine and have your own domain names so that to the outside world it looks like you're running your own server, but you can do that for a couple of hundred dollars a month, and maybe do that in the beginning as a trial and then see if it makes sense, see if there's any need to make it internal.

M: This site is behind the firewall.

Peter Morville: Okay.

M: This is for a corporate communication.

Peter Morville: Okay. So for a large corporation where you've got the firewall needs and the security, you're obviously going to want to do it internally. So does anyone have any suggestions to add to that list?

M: [inaudible]

Peter Morville: Right. Graphics tools and people to do the graphics.

M: Do you have some recommendations on graphics tools to use?

Peter Morville: That's not my area of expertise. The only thing I've used is Adobe *PhotoShop*.

M: [inaudible]

Peter Morville: I'm not sure. I don't know the answer to that.

Okay, well thanks everyone for coming. Hope you enjoyed the conference and I'll be around for a little while if anyone has any questions for me.

AT&T INTERCHANGE ONLINE NETWORKSM MEMBER AGREEMENT

AT&T Interchange Online NetworkSM (the "Network") is an online information and communication service, used by connecting your receiving and transmitting equipment (normally a personal computer with a modem connected to your telephone line) and client software used on your computer to the Network's telecommunications and computer facilities. The Network is operated by Interchange Network Company ("INC").

By completing the enrollment process you become an authorized user of the Network (a "Member"). You must agree to all of the terms and conditions contained in this Agreement and in the Network Operating Policies (the "Operating Policies") in order to become a Member, and continued acceptance of this Agreement and the Operating Policies is a condition of membership. The Operating Policies will follow this Member Agreement; scroll through the Member Agreement to view the Operating Policies.

BY COMPLETING THE ENROLLMENT PROCESS, YOU AGREE TO THE TERMS OF THIS AGREEMENT AND THE NETWORK OPERATING POLICIES, JUST AS IF YOU HAD SIGNED THIS AGREEMENT. IF YOU DO NOT WISH TO BE BOUND BY THIS AGREEMENT AND THE OPERATING POLICIES, PLEASE DO NOT COMPLETE THE ENROLLMENT PROCESS.

1. Membership Restricted to Individuals. Membership in the Network is restricted to individuals. INC may enter into billing arrangements with employers and other entities to pay the charges incurred by Interchange Members and to guarantee that the Members covered by such arrangements will abide by the terms of this Agreement and the Operating Policies. However, each Member, regardless of billing arrangement, must agree to abide by this Agreement and the Operating Policies.

2. Software License. The software provided to the Member to access the Network, and any enhancements, modifications or revisions thereto (the "Software"), are all copyrighted works registered under the U.S. copyright laws. The Software is licensed to the Member by INC only for Member's use in conjunction with Member's activities on the Network. INC retains ownership of the Software at all times. The Member may not assign or transfer his or her Membership or any of the files installed pursuant to the installation program. The Member may copy and distribute copies of the original program diskette and installation program. The Member may not decompile, reverse engineer or disassemble the Software or any part thereof or any manuals or documentation related thereto. This license will terminate automatically whenever membership in the Network is terminated for whatever reason.

3. Payment. Unless Member is accessing the Network via a multi-user corporate account, Member agrees to the following payment terms: Member agrees to pay all fees, connect time charges, minimum charges and other charges incurred by Member or on Member's account at the rates in effect during the billing period in which the charges were incurred, including charges for any purchases made through the Network and any surcharges incurred while using any supplemental networks or services other than the Network. Member shall pay all applicable taxes relating to use of the Network by Member. All payment shall be made by Member in accordance with the provisions of the billing option selected by Member. Member's right to use the Network is subject to any limits established by the relevant Network service to which Member is subscribing (a "Network Service"), INC or by Member's credit card issuer if Member's account is billed to a credit card account. Each Network Service reserves the right to

change the amount of any fee or charge for that Network Service, and to institute new fees or charges, effective upon thirty (30) days notice to its Member.

4. Equipment. Member must provide, at Member's own cost, all telephone and other equipment and services (other than the Software) necessary to access the Network.

5. Operating Policies. The Operating Policies of the Network set forth the rules that govern Member activity on every Network Service. As they may be amended by INC from time to time, they are a part of the contract between INC and Network Members. INC reserves the right to change the Operating Policies at any time without notice to Member; however, notice of any changes to the Operating Policies will be published on the Network promptly upon implementation of the change. The Operating Policies can be viewed on screen at any time by clicking on the "Operating Policies" icon in the Member Support area. Member's failure to comply with the Operating Policies may result in termination of Member's membership.

6. Disclaimer of Warranty; Limitation of Liability. INC makes no warranties with respect to the Software, any documentation provided with the Software, or any services performed by the Software and/or information contained therein. No publisher of any Network Service (a "Network Publisher"), dealer, distributor, agent or employee of INC has the right to increase the scope of this warranty, and no oral or written information or advice given by any Network Publisher, or INC's dealers, distributors, agents, or employees shall create a warranty or in any way increase the scope of this warranty.

Neither INC nor any Network Publisher warrants or guarantees the accuracy or completeness of any Network database or any information published or accessible on the Network, including information in any Network Service. Although INC and Network Publishers intend to take reasonable steps to screen uploaded files for infection by viruses, worms, Trojan horses or other code manifesting contaminating or destructive properties before making such files available for Member downloading, neither INC nor any Network Publisher can guarantee that any file available for downloading will be free of infection. Accordingly, INC and its Network Publishers cannot and do not guarantee or warrant that such files will be free of such properties. The entire risk as to the quality and performance of the Network, the quality of any related services, and the accuracy of any information, or quality of any software published on the Network is with the Member.

INC does not warrant that the functions or services performed by the Software or the Network will be uninterrupted or error-free or that defects in the Network or Software will be corrected. The Network and the Software are provided on an "as is, as available" basis. Neither INC nor any Network Publisher makes any warranties, express (except as expressly provided herein) or implied, including, without limitation, those of merchantability and fitness for a particular purpose, with respect to the Network, the Software, any Network Service, any information or software published on the Network, or any products or services sold through the Network.

In no event will INC or its Network Publishers be liable (i) for any incidental, consequential, or indirect damages (including, but not limited to, damages for loss of business profits, business interruption, loss of programs or information, and the like) arising out of the use of or inability to use the Network, the Software, the disk(s) on which the Software is recorded, or any information, software, or any services provided on the Network or downloaded from the Network, even if INC, a Network Publisher, or their respective authorized representatives have been advised of the possibility of such damages, or (ii) for any claim attributable to errors, omissions, or other inaccuracies published on any Network Service or any software contained in any software library contained in any Network Service and/or downloaded from any Network Service.

Because some states do not allow the exclusion or limitation of liability for consequential or incidental damages, the above limitation may not apply to you. In such states, INC's and its respective Network Publishers' liability is limited to the greatest extent permitted by law.

Each Member is responsible for implementing sufficient procedures and checkpoints to satisfy his or her particular requirements for accuracy of data input and output, and for maintaining a means external to the Network for the reconstruction of any lost data.

7. Reproduction of Information. Member may not reproduce, redistribute, retransmit, publish or commercially exploit any information, software or other content which Member receives through the Network, unless that action is expressly permitted under the Operating Policies.

8. Indemnification. Member agrees to indemnify, defend and hold harmless INC, its affiliated companies, licensors, employees, agents, Network Publishers and any third party information providers to the Network from and against all losses, expenses, damages and costs, including reasonable attorneys' fees, resulting from any violation of this Agreement (including the Operating Policies then in force), or any activity related to Member's account (including negligent or wrongful conduct) by the Member or any other person accessing the Network using the Member's Network account.

9. Third Party Rights. The provisions of paragraphs 6 (Disclaimer of Warranty), 7 (Reproduction of Information), and 8 (Indemnification) are for the benefit of INC, Network Publishers and their respective non-Member licensors, employees, agents and any non-Member third party information providers to the Network. Each of these individuals or entities shall have the right to assert and enforce those provisions directly against a Member directly on its own behalf.

10. Termination. This Agreement, the license provided herein, and Member's right to use this Network and the Software may be terminated at any time for any reason without notice by INC or Member. The provisions of paragraphs 3 (Payment), 6 (Disclaimer of Warranty), 7 (Reproduction of Information), 8 (Indemnification), and 9 (Third Party Rights) shall survive any termination of this Agreement.

11. General Provisions. Any provision or condition in any purchase order, voucher or other memorandum received by the Member in connection with the Network which is in any way inconsistent with, or adds to, the provisions of this Agreement is null and void. Neither the parties' course of conduct or trade practice will modify the terms of this Agreement or the Operating Policies. If any provision of this Agreement or the Operating Policies is determined by a court of competent jurisdiction to be invalid, all other terms and conditions shall remain in full force and effect.

12. Governing Law. This Agreement, the relationship between Member and INC resulting from this Agreement, and the resolution of any dispute arising out of that relationship shall all be governed and construed in accordance with the laws of the Commonwealth of Massachusetts applicable to agreements made and to be performed in Massachusetts. Member agrees that any legal action or proceeding between INC and Member for any purpose concerning this Agreement or the parties' obligations hereunder shall be brought exclusively in a federal or state court of competent jurisdiction sitting in Suffolk or Middlesex County, Massachusetts. Network Publishers shall have the right to determine jurisdiction of any dispute between that Network Publisher and any Member by notice to that Member.

13. Restricted Rights. The Software is provided with RESTRICTED RIGHTS. Use, duplication, or disclosure by employees of the Federal Government is subject to restrictions as set forth in subparagraph (c)(1)(ii) of The Rights in Technical Data and Computer Software clause at DFARS 252.227-7013 or in subparagraphs c(1) and (2) of the Commercial Computer Software – Restricted Rights at 48 CFR 52.227-19, as applicable. The manufacturer of the Software is AT&T Interchange Online Network, 25 First Street, Cambridge, MA 02141.

14. Restrictions on Export of Software. Member shall not, directly or indirectly, export or reexport the Software to any of the following countries: Albania, Armenia, Azerbaijan, Belarus, Bulgaria, Cambodia, Cuba, Estonia, Georgia, Iran, Iraq, Kazakhstan, Kyrgystan, Laos, Latvia, Libya, Lithuania, Mongolia, North Korea, People's Republic of China, Romania, Russia, Syria, Tajikistan, Turkmenistan, Ukraine, Uzbekistan, Vietnam, or Yugoslavia. The terms "export" and "reexport" mean transferring or releasing to another country or to a national of another country the Software by any means -- physical, electronic or otherwise. In the event that Member's membership to the Network and Member's license to the Software are terminated for any reason, Member shall continue to be bound to the restrictions on export contained in this paragraph.

15. Trademarks. AT&T, Interchange, and Interchange Online Network are service marks of AT&T. All rights reserved. All other trademarks appearing on the Network are owned by their respective companies.

AT&T INTERCHANGE ONLINE NETWORKSM

OPERATING POLICIES

AT&T Interchange Online NetworkSM (the "Network") has as its goal the transmission and exchange of useful data and the establishment of a community of members sharing and contributing to that data. Interchange Network Company ("INC"), the operator of the Network, has established policies to govern all members' conduct on the Network. These policies are subject to revision at any time by INC, but INC intends to notify all members over the Network promptly of any changes. Your acceptance of these policies is a condition of membership. Your failure to comply with these policies may result in termination of your membership on the Network.

1. Membership Requirements.

You must be an individual at least 18 years of age to enroll as a member (a "Member") of any service published on the Network (a "Network Service"). You must enroll on the Network under your own name. Please inform INC promptly if there is any change in the information which you provided to INC at the time of enrollment, including change of address and any credit, debit or charge card numbers and expiration dates.

The Network and your membership are to be used only by you and members of your immediate family. Unless you have INC's express written consent, you may not resell, assign or transfer your membership to anyone else. You may not permit any person other than yourself or your immediate family members to access the Network for any purpose using your name or account. You are personally responsible for all use of the Network under your account identification number ("ID") (including payment for any orders of goods or services from any Network Service or third party vendors and including liability for any harm caused by any material uploaded to any part of the Network).

2. Fees and Payment.

You must elect a method of payment at the time of enrollment. You are responsible for all charges (including applicable taxes) to your account. All fees and charges are payable in accordance with billing terms in effect at the time the fee or charge becomes payable. Current fees and charges are posted in the Member Support area of the Network. Each Network Service reserves the right to change the amount of, or basis for determining, any fees or charges for that Network Service, and to institute new fees or charges, effective upon thirty (30) days notice to its Members.

You are responsible for providing and maintaining the communications equipment (including personal computer and modem) and telephone services required for connecting and using the Network. INC will provide telephone numbers for connecting to the Network. You are responsible for all telephone fees and charges, including per-minute, unit surcharges and equipment, or line costs incurred by you, associated with the use of the telephone number(s) selected. Any disputes or problems regarding phone service are strictly between you and your local phone company or long-distance service provider.

If you have reason to believe that your account is no longer secure (i.e. in the event of a loss, theft or unauthorized disclosure or use of your ID, password, or any credit, debit or charge card number stored on the Network), you should promptly change your password and inform INC of the problem to avoid possible liability for any fraudulent charges to your account. Until INC is notified (by notice given as described in Section 4 or by telephone at 1-800-299-9699), you will remain responsible for any unauthorized use of the Network occurring under your ID.

3. Member IDs and Passwords.

Upon your enrollment as a Member, you will choose a unique ID; in addition, you must also choose a password at the time of enrollment. You must use both your ID and your password in order to gain access to the Network. Anyone who knows both your ID and your password can gain access to your personal information and misuse it (and incur charges which you may be responsible for), so all Members are advised to keep their passwords secret. You are advised to choose a password that is not obvious (for example, do not choose your name as a password), and we also advise you to change your password frequently. Instructions regarding changes to your password are posted in the Member Support area of the Network. If you forget your password, INC will disclose it to you as long as its security procedures are met.

You may not use another Member's ID. Unauthorized use of another Member's ID or password are grounds for termination of your Membership, and may be a violation of law.

4. Notice.

INC may deliver notice to Members by means of: electronic mail on the Network, a general notice on the Network, or by written communication delivered by first class U.S. mail to each Member's address on record in INC's account information. You may give notice to INC at any time:

- (i) via electronic mail to Member Support;
- (ii) by letter telecopied to INC at the following fax number: (617) 252-5525; or
- (iii) by letter delivered by first class postage prepaid U.S. mail or overnight courier to INC at the following address:

AT&T Interchange Online Network Member Support
25 First Street
Cambridge, MA 02141

5. Information on the Network.

It is the policy of the Network to encourage candid, open discussion of topics of interest to Members. Members should feel free to express their views and to be accountable to their fellow Members for those views.

Unlike print publications, however, Member participation in discussions on any Network Service and in communications with other Members through electronic mail occurs in real time. INC cannot and does not intend to screen Member messages in advance. In order to maintain a service that meets the needs of the Members and avoids the harm that can result from the publication of statements that are false, malicious, or violative of the rights of others, it is necessary to establish certain rules to protect against abuse. Disregard for these rules may result in the removal of uploads from the Network and/or termination of Membership.

- (i) Except where and when specifically permitted by a specific Network Service, you may not upload any messages, data or programs anonymously or under a false name. Nor may you permit any other person (other than a secretary, assistant or other agent acting on your behalf and subject to your supervision) to access the Network for any purpose using your account or ID.
- (ii) Members may not upload any information which is libelous, defamatory or which discloses private or personal matters concerning any person. Members may not upload any messages, data, images or programs which are obscene or pornographic.
- (iii) Members may not upload any messages, data, images or programs that would violate the property rights of others, including unauthorized copyrighted text, images or programs, trade secrets or other confidential proprietary information, and trademarks or service marks used in an infringing fashion. Please refer to Section 9 (Copyright and License) of these Operating Policies for further information regarding copyright rights in material uploaded to the Network.
- (iv) Members may not upload any files which contain viruses, worms, “Trojan horses” or any other contaminating or destructive features.
- (v) Members may not use the Network as a forum for “hate speech.” It is not the Network’s intent to discourage Members from taking controversial positions or expressing vigorously what may be unpopular views; however, the operator of each Network Service (a “Network Publisher”) reserves the right to remove uploads containing racial, ethnic or religious slurs or similar epithets, or advocating violence, or other language that is deeply and widely offensive. In addition, each Network Publisher reserves the right to take such other action as it deems appropriate in such cases, including the termination of membership.
- (vi) Except where expressly permitted by a Network Service, Members may not publish on or over the Network any information, software or other content which contains any charity requests, petitions for signatures, advertising or any solicitation of other members to use goods or services, without prior express approval of the relevant Network Publisher.
- (vii) Members may not use the facilities and capabilities of the Network to conduct any activity or solicit the performance of any illegal activity or other activity which infringes the rights of INC, any Network Publisher, other Members, merchants or information providers on the Network.

In light of its policy of encouraging candid, open exchanges of views by its Members and the rapid distribution of information originating from many sources, Network Publishers cannot determine in advance the accuracy of information that may be uploaded to the Network.

Accordingly, Network Publishers cannot and do not guarantee the accuracy or completeness of any database on the Network, of the information contained in any such database or of any statement uploaded to the Network by any Member.

Neither INC nor any Network Publisher endorses or is responsible for any statement, opinion, advice given or made on the Network by anyone other than authorized INC and/or Network Publisher spokespersons. Experts and sysops on the Network are not authorized spokespersons.

Opinions, advice and all other information expressed by Network Publishers and information providers represent the providers' own views and not necessarily those of INC, and Members rely on such information at their own risk. Members are urged to seek professional advice for specific, individual situations and not rely solely on advice or opinions given on the Network.

Neither INC nor any Network Publisher guarantees that any software uploaded to and published on the Network will be free of viruses, worms, "Trojan horses" or other contaminating or destructive features, although INC and its Network Publishers intend to take reasonable steps to attempt to screen such uploads before making them available for downloading. There is no fail-safe screening procedure that will catch all destructive code and INC and its Network Publishers cannot and will not be responsible if any such code passes through the screening procedures that INC or a Network Publisher follows and infects a Member's computer.

6. Electronic Mail.

Electronic mail ("mail") is a private electronic message sent by a Member or by INC or a Network Publisher to another Member or user of the Network. Once it has been read, it is retained by INC for seven (7) days. UNREAD MAIL TO MEMBERS IS AUTOMATICALLY DELETED THIRTY (30) DAYS AFTER THE DATE SENT. INC will retain unread mail for any canceled Network account until (a) the account is re-opened and the mail is read, (b) thirty (30) days after the mail was sent, or (c) thirty (30) days after the date the account is cancelled, whichever is earliest.

INC will not intentionally inspect the contents of mail sent by one Member to an identified addressee, or disclose such contents to other than the sender, or addressee, without the consent of the sender or the addressee, unless: (a) INC is required to do so by law (for example, in response to a lawful subpoena or court order), (b) such inspection or disclosure is necessary for the provision of mail service (for example, in connection with system maintenance or disaster recovery) or to the protection of the rights or property of INC, or (c) the mail is disclosed to INC by the recipient or the originator of the mail.

The rules of the Network prohibit any Member from harassing other Members with unwanted mail messages, including messages that are obscene, offensive or otherwise inappropriate or that are sent after the sender learns that the recipient does not wish to receive such messages. Members who receive such messages are encouraged to forward such messages to Member Support with any pertinent information concerning them. By forwarding mail message(s) to Member Support, a Member consents to review by INC personnel of original database records of the mail message. Following such review, INC will consider the complaint and take such action as INC, in its sole discretion, may deem appropriate.

INC, at its sole discretion, reserves the right to immediately terminate, without notice, the membership of any Member of any Network Service who misuses the Network's electronic mail.

7. Discussion Areas.

The content of any statement or information which is transmitted for posting in a discussion area should be consistent with the rules set forth in Section 5 (Information on the Network) of these Operating Policies and not violate the rights of others.

Each Network Publisher reserves the right to attach to any uploads related or opposing viewpoints, responses or other information as the Network Publisher in its sole discretion deems appropriate. Members who believe that a contribution to a discussion area violates the rules set forth in these Operating Policies are encouraged to contact either the system operator ("sysop") for the particular discussion area or Member Support. Violation of these rules may be the basis for termination of Membership.

Although Network Publishers and sysops monitoring Network discussion areas do not intend to engage in any prior review of member notes posted to discussion areas, each Network Publisher reserves the right in its sole discretion to edit, delete or redirect any information, software or other content uploaded to that Network Service (including Member uploads to discussion areas), regardless of whether the information, software or other content violates the rules for content described in Section 5 of these Operating Policies.

8. Software Libraries.

The Network and each Network Service may maintain software libraries ("Software Libraries") for Members' use. INC maintains all Software Libraries located in the "Interchange Central™" part of the Network ("Core Software Libraries"). Network Publishers maintain all Software Libraries on their respective Network Services. In connection with uploads to a Software Library, the uploading Member will be required to complete an information form regarding the uploaded data. The executed form constitutes an agreement that (i) the uploading Member either is the copyright holder of the uploaded data or has any copyright holder's express permission to contribute the data to the Software Library under the terms set forth in the Operating Policies, (ii) uploading the data and permitting Members to download it from the Software Library will not violate the copyright, trademark, trade secret, ownership or other rights of any person, (iii) the uploading Member will indemnify and hold INC and the relevant Network Publisher(s) harmless from any and all liability resulting from INC's or such Network Publisher's publication, distribution or redistribution of the uploaded data or the use of the data by any person (including liability resulting from any virus, worm, "Trojan horse" or other contaminating or destructive feature of the data), and (iv) that INC and the Network Publisher obtains the rights in the data set forth in Section 9 of the Operating Policies. INC and each Network Publisher reserves the right, in its sole discretion, to refuse posting of uploaded data in any Software Library, and to remove such data from any Software Library as it deems appropriate.

Each Network Publisher will take such steps as it deems appropriate to screen uploaded data for infection by viruses, worms, "Trojan horses" or other contaminating or destructive features before making such programs available for downloading. Because of the variety of such programs and the limitations in available virus detection tools, there is no way to be certain that a Network Publisher's screening procedures will be effective in every instance. **Neither INC nor any Network Publisher, therefore, warrant or guarantee that data made available for downloading from the Network and/or any Network Service will be free of viruses, worms, "Trojan horses" or other contaminating or destructive features, and no Network Publisher will be responsible for any damages or harm attributable to such features. Each Network Publisher encourages all Members to scan for viruses all programs they intend to load, including programs downloaded from any Software Library.**

Each Network Publisher, at its sole discretion, further reserves the right to terminate the membership of any Member who fails to comply with the rules for the Software Libraries.

9. Copyright and License.

The entire contents of the Network are copyrighted as a collective work under the United States copyright laws. The owner of the copyright in the collective work is INC. The entire contents of each Network Service are also copyrighted as a collective work under the United States copyright laws. The owner of the copyright in each collective work is the Network Publisher of that Network Service. The copying, redistribution, or publication of any part of the Network is prohibited, except as expressly provided below.

A Member who uploads any file to the Network for inclusion in any Software Library by such act grants (and represents and warrants that he or she is authorized to grant) to the Network Publisher of the Network Service to which such file was uploaded an irrevocable, non-exclusive, royalty-free license to publish, distribute and redistribute that file in any medium, whether now known or hereafter invented, including without limitation, databases distributed via computer facilities and in storage media such as a CD-ROM. For any files designated by the uploading Member as "shareware", the Network Publisher will retain and distribute in connection with such publication, distribution or redistribution any copyright notices and any license terms included by such Members.

Each Member who places information or any other content (other than any file for inclusion in any Software Library) in the public areas of any Network Service grants the Network Publisher of the Network Service to which such content was uploaded an irrevocable, non-exclusive, royalty-free, perpetual worldwide right and license to use, review, edit, copy, publish, distribute, and translate the file, information or other content in any medium, whether now known or hereafter invented, including without limitation databases distributed via computer facilities and in local storage media such as CD-ROM. In addition, each Member uploading material to any Network Service grants to all other Members permission to use all or part of the material for non-commercial purposes (as defined below), and to make copies of the material for backup purposes. Members have no other rights to copy any material downloaded from the Network. **Subject to this grant of rights, any Member who places information or other content (including software for inclusion in any Software Library) on the Network retains any rights that Member may have in that content.** Each Network Publisher agrees that it will retain any copyright notices on any content published or distributed by that Network Publisher pursuant to this license grant.

Members may not upload to the Network any copyrighted material (including photographs, video, animation, text, software programs, graphics or sound files) without the express permission of any copyright owner or the owner's agent. Only the owner or a representative designated by the owner may upload copyrighted material to the Network. By submitting material to a public area, a Member asserts that the material is his or her own, is licensed to be uploaded and downloaded by Members, is in the public domain, or is otherwise free of copyright or other restrictions. Neither INC nor Network Providers guarantee that material uploaded to the Network has been uploaded with the permission of the copyright holder; therefore, neither INC nor any Network Provider guarantees that such material may be freely used.

Each Member may download material from the Network for his or her own non-commercial use. This non-commercial use restriction means that a Member may use in connection with the internal operations of Member's business any material which Member has downloaded from the Network, but the Member is not allowed to redistribute that material over any network (including any local area network), nor sell or offer for sale that material. Members may not post any material downloaded from the Network to any other online service (including any bulletin board services or the Internet) without the express permission of the copyright holder. Member may make: (a) one machine readable copy, (b) one backup copy, and (c) one print copy of any material downloaded from the Network. Any other copying, or any redistribution or publication

of any downloaded material must be with the express permission of the relevant Network Publisher and the owner(s) or authorized person(s), if other than any Network Publisher. Permission must be specified in the material downloaded, on the Network, or must be obtained directly from the relevant Network Publisher and the owner(s), if other than a Network Publisher. In any permitted copying, redistribution or publication of copyrighted material, any changes to or deletion of any copyright notice are prohibited.

With respect to shareware programs, only the owner or representative authorized by the owner may upload shareware programs to the Network. Members may download shareware programs for their own use, subject to the terms provided by the owner. Members may only redistribute a shareware program if the terms displayed in the shareware program allow such redistribution or with permission of the owner or authorized representative of the owner. Any obligations set forth in the shareware license are solely the responsibility of the downloading Members.

Members may upload public domain programs (including “freeware”) to the Network. Members may download public domain programs for their own use. Members assume all risks regarding the determination of whether a program is in the public domain.

Each Network Publisher reserves the right to remove from the Network immediately any material which it believes may violate any copyright or other third party rights and the Member uploading this material may have his or her Membership on the Network terminated.

Setting Up ISDN Network Access

An Internet Service Provider's Perspective

InterNex

Robert Berger
Chief Technology Officer

Helping Businesses do Business on the InternetSM
First Commercial ISDN Internet Service in the US

ISDN: Minimum Speed for Internet Access

- The Web can be a production tool for work
- Enough bandwidth to support LAN connections
- Fast call setup/tear down simulates permanent connection

New Generation Network Needed

- Still requires local numbers for low cost dialup
- Assume 128kbps is minimum customer speed
- Total Network Bandwidth an order of magnitude higher

Match Technology to Scale

- Switched calls to Packet traffic ASAP
- PRI minimizes wire complexity
- Proper Equipment Selection

Switched Calls to Packet ASAP

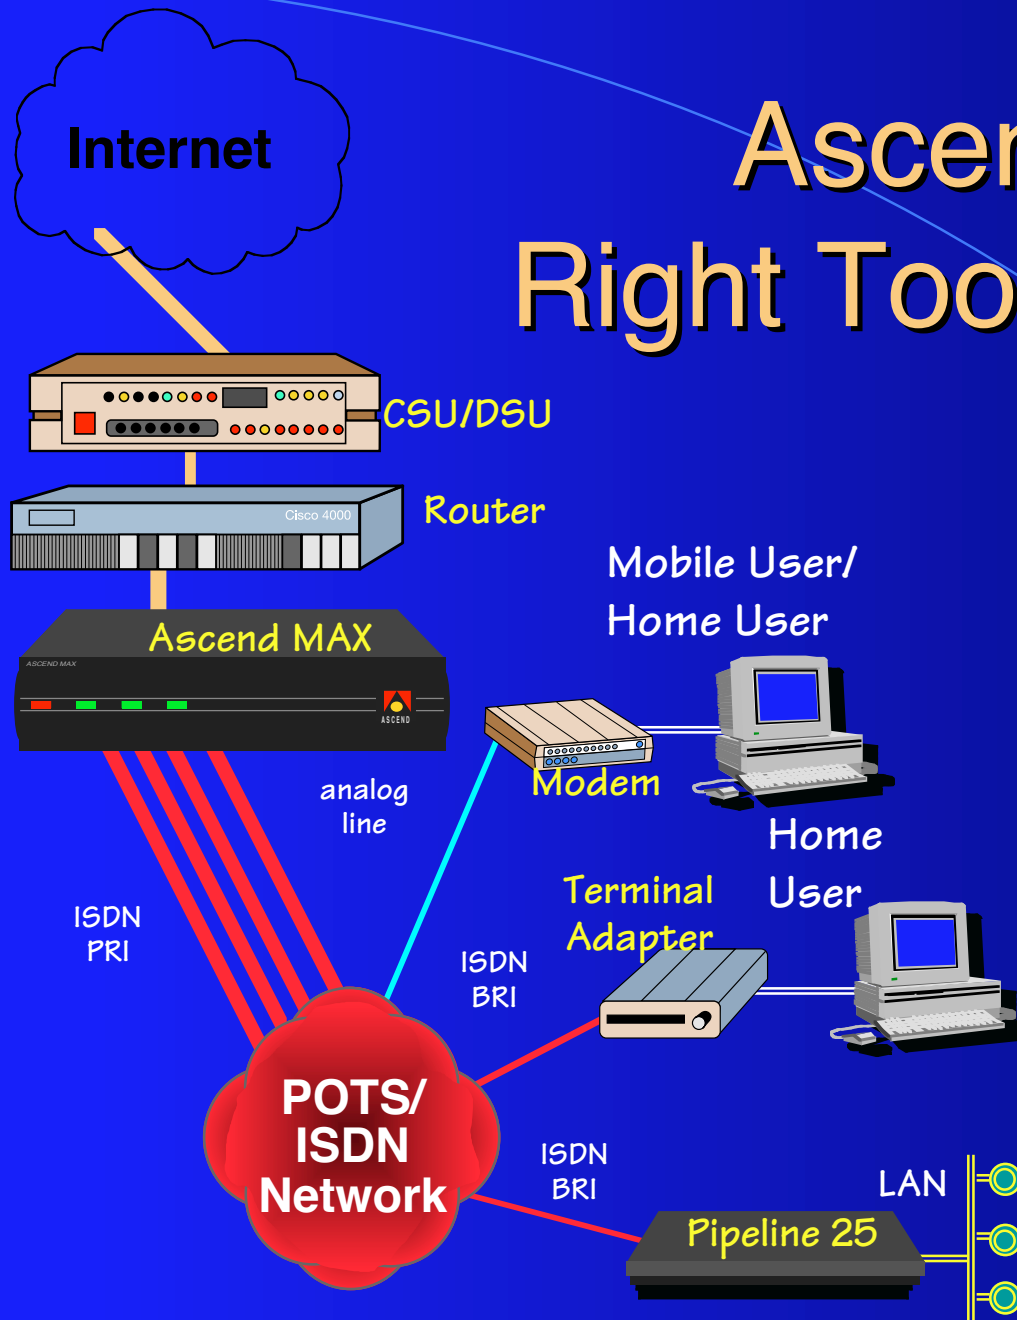

- Switched calls (POTS, ISDN) utilize resources (trunks, switches) even when no packets flow.
- Packet transport (Frame Relay, SMDS, ATM) win from statistical multiplexing.
- Conservative 4:1 ratio of switched to packet capacity

Traditional POTS POP

- How many wires and boxes does it take to handle 92 analog modems?

Ascend Max: Right Tool for the Job

- High Density
- Supports most of the key standards
- Can mix Analog and ISDN on PRI

Advantages of the Max

- Up to 4 PRIs + V.35 port
- Up to 48 simultaneous V.34 analog modem sessions
- Up to 92 simultaneous B Channel sessions
- Flexible Security

Limitations of the Max

- Limited Routing Protocol Support
 - No OSPF or Multicast
- Requires external router for sophisticated routing of backhaul link
- Does not support D Channel Transport
- Hard to debug connection problems

Security

- PAP, CHAP dialup negotiation
- Call Back, Calling Line ID
- Radius Server
- Token(Security Dynamics SecurID®, Enigma Logics SAFEWORD®)
- Packet Filtering on a per user basis

Accounting

- Radius Accounting
- Requires lots of work to extract valid billing info
- Software for billing is just now getting stable

InterNex Modular POP

- Scalable
- Pushes ALL services as close to the customer as possible
 - Email, News, DNS, Web Caching
- Rapidly Deployable
- Remotely Managed and Monitored

POP Architecture

- Router & CSU/DSU
 - Backhaul, OSPF Routing
- ISDN/Modem Router
- Local Sparc 20 Server
 - News, DNS, EMail, Caching. Diagnostics
- Terminal Server
 - Remote Console
 - Power Reset
- RMON
 - Utilization Monitoring

Location, Location, Location

- POPs have a 12 mile local calling circle
- Need lots of them to cover a region
 - 13 to cover most of the Bay Area
- Finding the right CO's with the right facilities is key
- Finding physical space for POP is not fun
- Can be expensive!

InterNex: Internet & VPN

- InterNex has the POP coverage
 - Bay Area
 - LA
 - Fresno
 - Sacramento Soon
- Local ISDN Dialup
 - Internet
 - Telecommuting
- Don't Reinvent the Wheel!

The Wireless Future

Larry Bestor, Chairman
American Technologies, Inc.

AGENDA

- **Overview - 5 min.**
- **Current capabilities and uses - 10 min.**
- **Hardware devices - 5 min.**
- **Software applications - 5 min.**
- **Communications networks - 5 min.**
- **Future capabilities and uses - 10 min.**
- **Adjourn**

INTRODUCTION

- Wireless Access to the Internet
-
- What are the uses of this technology now?
-
- What's in store for the future?

OVERVIEW

- System diagram
- GPS satellites, GEO satellites, LEO satellites, dispatch center, mobile units, radios, pagers, Internet network
- Software
- How the pieces fit together

DEFINITIONS

- GPS - Global Positioning System satellites
- GEO's - Geostationary satellites
- LEO's - Low Earth Orbit satellites
- WANS - Wide Area Networks

Presentation

C++ Techniques for Building Communication Protocol Libraries - Tutorial 3 -

Michael Baldwin
baldwin@dart.com
<http://www.dart.com>
Fall Internet World '95
October 30, 1995

About the Presenter

- ◆ Developed first Windows 2.0 TCP/IP app in 1990 using Excelan TCP/IP NIC
- ◆ Commercialized first WINSOCK TCP/IP protocol library Feb 1993 (GCP++)
- ◆ Released PowerTCP v 1.0 libraries Aug 1994 (DLLs, C++ Class Libraries, VBXs)
- ◆ TCP, TELNET, FTP, SMTP, POP3, UDP, VT220, TFTP, SNMP now shipping. C++ Class Libraries, DLLs, VBXs, OCXs.

Session Goals

- ✦ How to use C++ Class mechanisms to support communication protocol implementation
 - class specialization (e.g. TCP/TELNET)
 - encapsulation (e.g. FTP)
 - virtual functions for event notification
 - virtual functions for base class information needs

Presentation Overview

- ◆ Section 1 - Review of C++ mechanisms ... specialization, encapsulation, virtual functions
- ◆ Section 2 - Application of C++ mechanisms to Communications Software Development
- ◆ Section 3 - MSVC demonstration using PowerTCP libraries

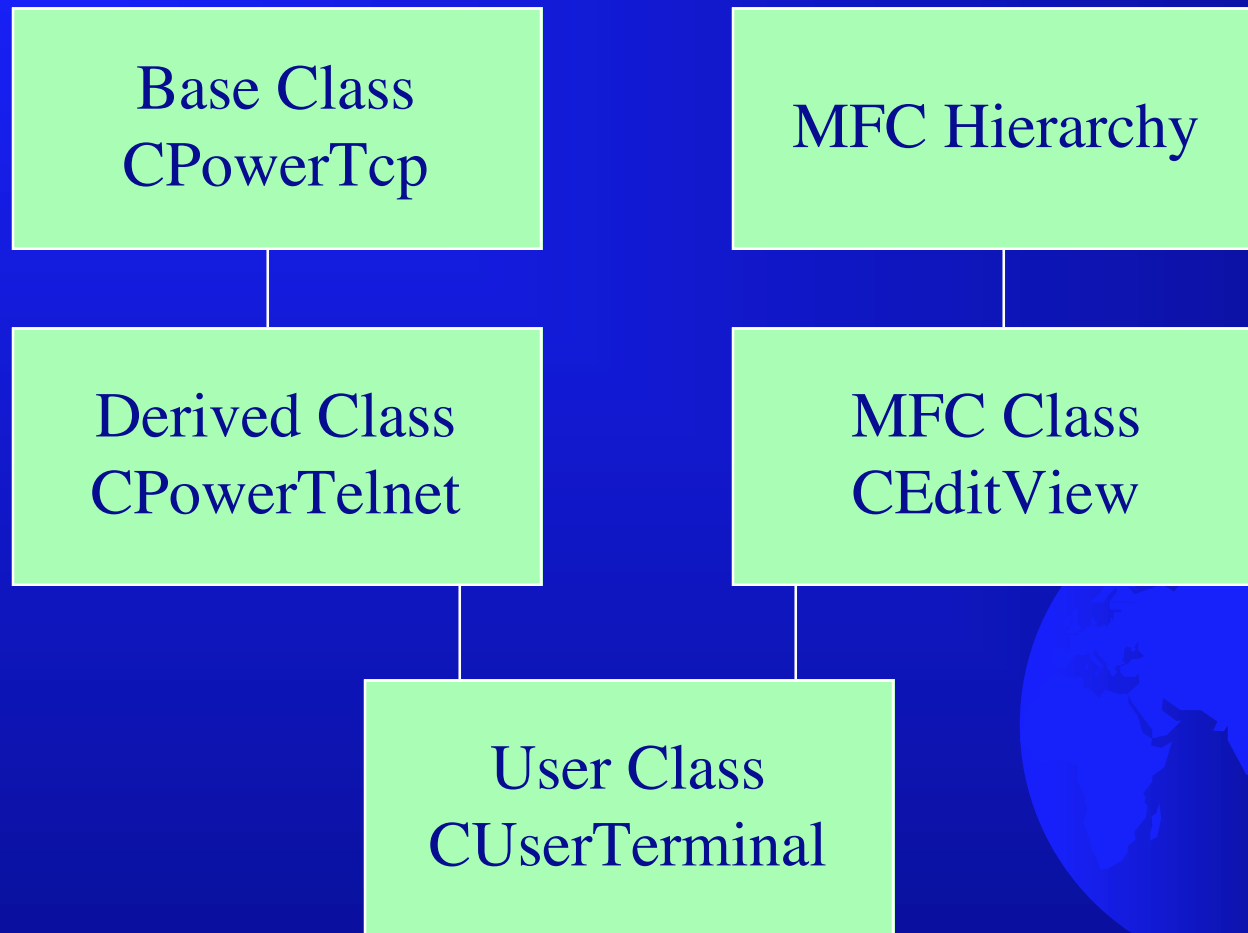

Review of C++ Mechanisms

Section 1

Class Specialization

Encapsulation

Base Class
CPowerTelnet

User Class
CUserTelnet

```
private:  
    CEditView Terminal
```

Virtual Functions for Derived Class Event Notification

Base Class
CPowerTelnet

```
virtual void RecvEvent  
    ( LPBYTE Data, UINT ByteCnt );
```

User Class
CUserTelnet

```
void RecvEvent ( LPBYTE Data, UINT ByteCnt )  
{  
    // your code to process data goes here  
}
```

Virtual Functions for Base Class Queries

Base Class
CWinsock

```
virtual PT_TYPE Protocol ( void ) = 0 ;
```

Derived Class
CPowerTelnet

```
PT_TYPE Protocol ( void )  
{  
    return PT_TELNET;  
}
```

Application of C++ Mechanisms to Communications Software Development

Section 2

Transmission Control Protocol

- ✦ connection oriented ... stream ... no record blocking ... “bursty” communications
- ✦ Reliable end-to-end communications
- ✦ Connections can be established as:
 - “active” ... a client makes active connections
 - “passive” ... a server accepts connections

Typical Active Connect

- ◆ create a socket, bind it to a port/address, set options and notification choices, launch connect request
- ◆ catch notification of successful connect
- ◆ send/recv data according to the upper layer protocol being implemented
- ◆ close connection

TCP Stream Class

```
class CPowerTcp
{
protected:
// notification functions from Tcp follow...
virtual void ConnectEvent (LPCSTR RemoteDotAddr, WORD RemotePort,
                           LPCSTR LocalDotAddr, WORD LocalPort, LPCSTR LocalName);
virtual void RecvEvent (LPBYTE Data, UINT ByteCnt);
virtual void SendEvent (DWORD DataTag);
virtual void ListenEvent (LPCSTR LocalDotAddr, WORD LocalPort, LPCSTR LocalName);
virtual void AcceptEvent (void);
virtual void ExceptionEvent (PT_EXCEPTION ErrorCode, LPCSTR ErrorDesc)=0;
public:
BOOL Connect (LPCSTR OemLicense, PT_FLAGS Flags, LPCSTR RemoteHost,
              WORD RemotePort, LPCSTR LocalDotAddr, WORD LocalPort);
BOOL Accept (LPCSTR OemLicense, PT_FLAGS Flags, CPowerTcp &Listener);
BOOL Send (LPVOID Data, UINT ByteCnt, BOOL Urgent, DWORD DataTag);
BOOL Recv (UINT MaxByteCnt);
BOOL Listen (LPCSTR OemLicense, PT_FLAGS Flags, LPCSTR LocalDotAddr,
             WORD LocalPort, WORD Timeout=0);
BOOL Close (BOOL NoDelay);
PT_STATE State (void);
CPowerTcp (HINSTANCE);
~CPowerTcp (void);
};
```

TELNET

- ✦ Used to “login” to a remote UNIX host
- ✦ Commands are embedded in the data stream
- ✦ Data must be parsed, searching for these sequences, which must be responded to*

* most hosts will halt communications, waiting for a response

Typical TELNET Session

- ♦ create TELNET connection (port 23)
- ♦ search for control sequences and respond to them with WILL, WONT, DO or DONT responses
- ♦ (usually) display data to user viewing ...
may implement terminal emulation
- ♦ (usually) send ascii data as user types
- ♦ close connection when complete

TELNET Class

```
class CPowerTelnet : public CPowerTcp
{
private:
    LPBYTE Search (LPBYTE ptr, BYTE ch, size_t limit);
    // Space for TELNET commands spanning receives
    BYTE CmdBuf[100];
    int CmdCnt;
    void CheckTelnetCmd(void);
    // assessor functions from PowerTcp follow...
    void RecvEvent (LPBYTE Data, UINT ByteCnt);
protected:
    // notification functions must be overridden by derived classes...
    virtual void TelnetRecvEvent (LPBYTE Data, UINT ByteCnt)=0;
    virtual void CmdEvent (BYTE Cmd, BYTE Option,
        LPBYTE SubOption, UINT SubOptionCnt);
public:
    BOOL SendCmd (BYTE Cmd, BYTE Option, LPBYTE SubOption,
        UINT SubOptionCnt, DWORD DataTag);
    CPowerTelnet (HINSTANCE);
    ~CPowerTelnet (void);
};
```

File Transfer Protocol (FTP)

- ✦ authentication support (user/password)
- ✦ most file manager features are implemented (directory listings, change directory)
- ✦ binary and ascii transfers
 - binary transfers an exact image
 - ascii uses CR/LF for every end-of-line
- ✦ benefits - ubiquitous, LCD
- ✦ drawbacks - inefficient for numerous files

Typical FTP Transfer

- ✦ create TELNET control connection
- ✦ pass user and login information (control)
- ✦ create TCP “listening” daemon
- ✦ pass address and port of daemon (control)
- ✦ pass instruction for file transfer (control)
- ✦ accept connection and transfer file data
- ✦ close data connection when complete
- ✦ close control connection when finished

FTP Class

```
class CPowerFtp
{
private:
    // references to Control, Listener, and Data are used so that FTP.HPP
    // does not have to be distributed
    CFtpControl &Control;
protected:
    // notification functions must be overridden by derived classes...
    // informs us of a successful connection and login
    virtual void ConnectEvent (LPCSTR RemoteDotAddr, WORD RemotePort,
        LPCSTR LocalDotAddr, WORD LocalPort, LPCSTR LocalName);
    // informs us of an exception
    virtual void LogEvent (LPCSTR Message)=0;
    // informs us that file or list data has been received
    virtual void RecvEvent (LPBYTE Data, UINT ByteCnt);
    // informs us that file is being spooled
    virtual void TransferEvent (FTP_COMMAND Command, DWORD BlockCnt,
        DWORD ByteCnt, LPSTR LocalFileSpec);
    // informs us that FTP has a reply
    virtual void ReplyEvent (FTP_STATUS Status, FTP_COMMAND LastCommand,
        int ReplyCode, LPCSTR ReplyStr)=0;
    // informs us that previously submitted data has been sent
    virtual void SendEvent (DWORD Tag);
    CPowerFtp (HINSTANCE);
    ~CPowerFtp (void);
};
```

Windows Sockets Specification

- Tutorial 11 -

How to Develop Internet-Aware Windows Applications

Michael Baldwin
baldwin@dart.com
<http://www.dart.com>
Fall Internet World '95
October 31, 1995

About the Presenter

- ◆ Developed first Windows 2.0 TCP/IP app in 1990 using Excelan TCP/IP NIC
- ◆ Commercialized first WINSOCK TCP/IP protocol library Feb 1993 (GCP++)
- ◆ Released PowerTCP v 1.0 libraries Aug 1994 (DLLs, C++ Class Libraries, VBXs)
- ◆ TCP, TELNET, FTP, SMTP, POP3, UDP, VT220, TFTP, SNMP now shipping. C++ Class Libraries, DLLs, VBXs, OCXs.

Session Goals

- ✦ TCP and UDP - Understanding of data communication basics
- ✦ TELNET and FTP - Understanding of how Upper-Layer Protocols are implemented
- ✦ What the WINSOCK specification is, why it is important, how to use it for TCP/UDP access
- ✦ How to access WINSOCK from VC++, non-Microsoft Compilers, Visual Basic, PowerBuilder, Delphi

Presentation Overview

- ◆ Section 1 - UDP and TCP basics. TELNET and FTP.
- ◆ Section 2 - WINSOCK history and benefits. WINSOCK 1.1 Details.
- ◆ Section 3 - Development Environments. Introduction to TCP/IP Protocol Libraries.

UDP, TCP, TELNET, FTP

Section 1

User Datagram Protocol

- ✦ connectionless...block oriented...no guaranteed delivery!
- ✦ packets are individually addressed, so a single port can address many others
- ✦ broadcast packets can be received by *all* hosts on local network physical segment
- ✦ you receive all packets addressed to the port you “bind” to

Typical UDP Session

- ✦ create a socket, bind it to a port/address, set options and notification choices
- ✦ send/recv data according to the upper layer protocol being implemented
- ✦ close socket

Transmission Control Protocol

- ✦ connection oriented ... stream ... no record blocking ... “bursty” communications
- ✦ Reliable end-to-end communications
- ✦ Connections can be established as:
 - “active” ... a client makes active connections
 - “passive” ... a server accepts connections

Typical Active Connect

- ◆ create a socket, bind it to a port/address, set options and notification choices, launch connect request
- ◆ catch notification of successful connect
- ◆ send/recv data according to the upper layer protocol being implemented
- ◆ close connection

Typical Passive Connect

- ♦ create a socket, bind it to a port/address, set options and notification choices, launch listen request
- ♦ catch notification of successful connect
- ♦ accept the new connection
- ♦ set up dynamic structures to handle support for multiple accepted connections
- ♦ close connection

TELNET

- ✦ Used to “login” to a remote UNIX host
- ✦ Commands are embedded in the data stream
- ✦ Data must be parsed, searching for these sequences, which must be responded to*

* most hosts will halt communications, waiting for a response

Typical TELNET Session

- ◆ create TELNET connection (port 23)
- ◆ search for control sequences and respond to them with WILL, WONT, DO or DONT responses
- ◆ (usually) display data to user viewing ...
may implement terminal emulation
- ◆ (usually) send ascii data as user types
- ◆ close connection when complete

File Transfer Protocol (FTP)

- ✦ authentication support (user/password)
- ✦ most file manager features are implemented (directory listings, change directory)
- ✦ binary and ascii transfers
 - binary transfers an exact image
 - ascii uses CR/LF for every end-of-line
- ✦ benefits - ubiquitous, LCD
- ✦ drawbacks - inefficient for numerous files

Typical FTP Transfer

- ♦ create TELNET control connection
- ♦ pass user and login information (control)
- ♦ create TCP “listening” daemon
- ♦ pass address and port of daemon (control)
- ♦ pass instruction for file transfer (control)
- ♦ accept connection and transfer file data
- ♦ close data connection when complete
- ♦ close control connection when finished

Windows Sockets 1.1

Section 2

A Little History

- ✦ Early DOS TCP/IP vendors for PC (80's): FTP Software and Excelan (EXOS products). Proprietary libraries.
- ✦ First TCP/IP vendor with a DLL: NetManage (1991). Proprietary libraries.
- ✦ Developers demand an API standard for DLL access...Windows Sockets is born in 1992.
- ✦ New players take the lead, vendors with market share drag their feet

Why is WINSOCK Important?

- ◆ Apps run on any TCP/IP transport supporting WINSOCK (NetManage, Distinct, Microsoft, OS2, Wollongong, FTP, Beame & Whiteside, DEC, etc.), **increasing your potential market**
- ◆ Market success encouraged MS to make it part of WFW, Windows NT, and Windows 95, **increasing your potential market**
- ◆ Version 2 will support addition transports, **again increasing your potential market**

Comm Software 101

- ✦ Synchronous Blocking functions: capture thread and return when function successful (typical in UNIX, but not DOS/Windows)
- ✦ Synchronous NonBlocking functions: capture thread and return quickly whether successful or not (typical polling in DOS)
- ✦ Asynchronous NonBlocking functions: event triggers call to function (typical event-driven system like Windows)

WINSOCK Communications

- ✦ can call blocking functions, but only one may be active at any time (OS limitation)
- ✦ can call non-blocking functions on a timer, but polling is inefficient
- ✦ recommended: let WINSOCK trigger successful connect, when more data can be sent, when data is present to receive - efficient and never interferes with other tasks

Typical Active Connect

- ◆ create a socket, bind it to a port/address, set options and notification choices, launch connect request
- ◆ catch notification of successful connect
- ◆ send/recv data according to the upper layer protocol being implemented
- ◆ close connection

socket ()

- ◆ specify SOCK_STREAM for a TCP socket
- ◆ specify SOCK_DGRAM for a UDP socket

bind ()

- ✦ when a socket is created, it is not yet associated with a local port or address
- ✦ bind() assigns an address and port to the socket prior to establishing TCP connections or use with UDP

WSAAsyncSelect ()

- ✦ preferred mechanism for notification of connect, close, recv data, readiness for writing, recv urgent data, incoming connection to accept
- ✦ recv data, recv urgent data, and incoming connections are “level triggered”

ioctlsocket ()

- ✦ used to enable/disable non-blocking operations
- ✦ used to determine the amount of data that can be read
- ✦ checks for urgent data to be read

connect ()

- ✦ create a connection to the specified host
- ✦ a blocking socket can capture the thread for seconds
- ✦ use select() to determine the completion of the connection request on a non-blocking socket -or-
- ✦ use WSAAsyncSelect() to have an event generated to signal completion

recv ()

- ✦ normally used to receive data on a TCP connection
- ✦ calling recv() copies received data into the buffer specified
- ✦ if a blocking socket, and no data is available, will capture thread until data is available
- ✦ a result of 0 bytes indicates a closed connection

send ()

- ✦ normally used to send data over TCP connections
- ✦ application must be prepared if all data is not buffered into the kernel buffers

closesocket ()

- ✦ closing a connected TCP socket involves handshaking with the remote host
- ✦ socket parameters are used to specify a hard close, a blocking graceful close, or a non-blocking graceful close (the system is trusted to close the connection even if your application is unloaded)

Typical Passive Connect

- ♦ create a socket, bind it to a port/address, set options and notification choices, launch listen request
- ♦ catch notification of successful connect
- ♦ accept the new connection
- ♦ set up structures to handle support for multiple accepted connections
- ♦ close connection

listen ()

- ✦ to make a passive connection, first create a socket then use listen() to allow the kernel to listen for incoming connections
- ✦ use accept() to create each connection

accept ()

- ✦ extracts the first connection on the queue of pending connections on the listening socket and returns a handle to the new socket
- ✦ new sockets are “spawned” as clients connect to the host
- ✦ an object-oriented development environment helps make this manageable

Typical UDP Session

- ✦ create a socket, bind it to a port/address, set options and notification choices
- ✦ send/recv data according to the upper layer protocol being implemented
- ✦ close socket

sendto ()

- ✦ normally used to send data over UDP sockets
- ✦ application must be prepared if all data is not buffered into the kernel buffers
- ✦ remote address and port must be specified, and may be used to send to multiple hosts
- ✦ broadcast address can be used to send to all hosts on the physical segment

recvfrom ()

- ✦ normally used to receive data on a UDP socket
- ✦ calling recv() copies received data into the buffer specified
- ✦ if a blocking socket, and no data is available, will capture thread until data is available
- ✦ also returns source address and port

select ()

- ◆ blocking notification technique
- ◆ recommend WSAAsyncSelect() be used instead

misc

- ✦ getpeername ()
- ✦ getsockname ()
- ✦ getsockopt ()
- ✦ setsockopt ()
- ✦ shutdown ()
- ✦ htonl ()
- ✦ htons ()
- ✦ ntohl ()
- ✦ ntohs ()
- ✦ inet_addr ()
- ✦ inet_ntoa ()

Database Routines

- ◆ getprotobyname()
- ◆ getprotobynumber()
- ◆ getservbyname()
- ◆ getservbyport()
- ◆ gethostbyaddr()
- ◆ gethostbyname()
- ◆ gethostname()
- ◆ WSAAsyncGetProtoByName()
- ◆ WSAAsyncGetProtoByNumber()
- ◆ WSAAsyncGetServByName()
- ◆ WSAAsyncGetServByPort()
- ◆ WSAAsyncGetHostByAddr()
- ◆ WSAAsyncGetHostByName()

Misc WSA Functions

- ✦ WSAStartup()
- ✦ WSACleanup()
- ✦ WSAGetLastError()
- ✦ WSASetLastError()
- ✦ WSACancelAsyncRequest()
- ✦ WSAIsBlocking()
- ✦ WSASetBlockingHook()
- ✦ WSAUnhookBlockingHook()
- ✦ WSACancelBlockingCall()

Using PowerTCP libraries

Emulator application	FTP application	Any other TCP/IP app
PowerTCP libraries: TCP, TELNET...		
TCP and UDP		
IP Protocol		
Data Link Layer		
Physical Layer		

Standard C
interface, C++
class, or VBX
interface

WINSOCK
interface

WINSOCK Interface

- ♦ Any C compiler not difficult
- ♦ MFC supplies CSocket Class Library
- ♦ Visual Basic - difficult to use asynchronous notification, but polling can work
- ♦ Delphi - difficult to establish “glue”, but can work with effort
- ♦ PowerBuilder - asynchronous notification impossible, but polling can work

Libraries that use WINSOCK

- ◆ High-level DLLs can simplify functionality to make interfacing easier
- ◆ Visual Basic Components can integrate WINSOCK into VB, PowerBuilder
- ◆ Delphi VCL Components can integrate WINSOCK into VB
- ◆ OLE Components can integrate WINSOCK into any environment with OLE Containers

Shareware Components

- ◆ dsSocket (Dolphin Systems), IPPORT (DevSoft) and other shareware products bridge the gap between WINSOCK and VBX environments
- ◆ low-cost or no-cost
- ◆ little or no support
- ◆ found on the `net, compuserve, etc.
- ◆ differing levels of quality

Commercial Components

- ◆ Technical support available
- ◆ Usually offer more value-add with Upper Layer Protocols (TELNET, FTP, etc)
- ◆ SDKs and Toolkits include comprehensive examples
- ◆ Toolkits \$298 - \$698 and charge user-based run-time licensing fees
- ◆ Some offer fixed-fee licensing

Commercial Library Vendors

- ◆ NetManage - tool use requires licensing of their run-time kernel
- ◆ Distinct - run-time extensions (licenses)
- ◆ Dart Communications - 3 options
 - run-time licenses
 - distribution license for unlimited distribution
 - OEM Partner Subscription includes annual maintenance and support

Final Thoughts...

- ♦ Internet Software ... great opportunities exist
- ♦ WINSOCK interface ... requires a great deal of testing over multiple stacks before you are “commercial grade”
- ♦ Visual Basic and Delphi ... great RAD environments!

Additional information...

- ♦ UNIX Network Programming, W. Richard Stevens, Prentice Hall
- ♦ sunsite.unc.edu
 - pub/micros/pc-stuff/ms-windows/winsock
- ♦ Douglas Comer has a series of TCP/IP protocol books

Europe—big place!

- ◆ 300 million people
- ◆ 15 countries in the EU
- ◆ Over thirty languages
- ◆ Distinct national identities
- ◆ Ancient culture

Huge technology gradient

- ◆ EU working to even out North/South differences
- ◆ Different regulatory regimes complicate things
- ◆ Uneven national wealth
- ◆ Lower per capita income

The regulatory mix

- ◆ UK leads in telecoms/media liberalisation
- ◆ US-style telco de-regulation
- ◆ Long-distance/local split
- ◆ Cable enters UK telephony
- ◆ Local loop now competitive
- ◆ Satellite TV has a large presence
- ◆ Cable passes only 20% of homes

Raw numbers

- ◆ 400,000 hosts in the UK
- ◆ Highest growth in Europe
- ◆ 1 million connected in the UK
- ◆ (4th Arpanet host in London)

The leapfrog effect

- ◆ Tiny legacy Internet user base
- ◆ Very few personal shell accounts
- ◆ Consumer market leaps straight to SLIP/PPP
- ◆ Huge boost for the web

The lesson from cable

- ◆ A laboratory for US firms
- ◆ Telephony delivers revenue fast
- ◆ New high-margin products on the horizon

The on-line landscape 1

◆ The web

- ◆ 80 access providers in the UK
- ◆ Local dial everywhere
- ◆ Mom & Pop to BT
- ◆ v34 everywhere

The Americans are coming!

- ◆ PSI buys EUNet GB
- ◆ UUNet bids for Pipex/Unipalm
 - ◆ (who gets their bandwidth?)
- ◆ Bandwidth partnerships across Europe
- ◆ Still room for more!

European creative resources

- ◆ Design
- ◆ Advertising
- ◆ Art/literature

The on-line landscape 2

- ◆ Commercial services
 - ◆ last year...
 - ◆ CompuServe

The online landscape 3

◆ Commercial services

◆ next year:

- ◆ CompuServe
- ◆ AOL/Bertelsmann
- ◆ Delphi
- ◆ MSN
- ◆ BT
- ◆ Many local variants

Europe Online

UK Online (Olivetti)

Prodigy/IBM

(eWorld)

Virgin

Who's developing content?

- ◆ Media owners

- ◆ The Telegraph

The BBC

- ◆ Corporates

- ◆ Lloyds Bank

Lufthansa

- ◆ Ad agencies

- ◆ Cordiant

Ogilvie & Mather

What's their model?

- ◆ Media owners
 - ◆ Like TV without rules
- ◆ Corporates
 - ◆ Billboards
- ◆ Ad agencies
 - ◆ Mass medium

Cultural differences

- ◆ Public service deeply embedded
- ◆ No concept of 'paid-for programming'
- ◆ Weird funding models
- ◆ Cynical audience

What do we want from you?

- ◆ Your bandwidth
- ◆ Your technical know-how
- ◆ Your entrepreneurial drive
- ◆ Your ATTITUDE

What do you get?

- ◆ Creativity
- ◆ Audience
- ◆ Compelling content
- ◆ 600 million eyeballs

A bridge-head in a growing market

- ◆ Spreading East
- ◆ 20 countries by 2000?
- ◆ The most diverse market in the world
- ◆ Internal trade barriers effectively down
- ◆ Investment-friendly environment

How to get involved

- ◆ Strategic partnership
- ◆ License your content product for Europe
- ◆ Source European content in Europe
- ◆ Get yourself a distributor

UK Internet trade body

◆ The IDA

- ◆ Media owners
- ◆ Production houses/content developers
- ◆ Ad agencies

Presentation

MAKING AND ENFORCING ELECTRONIC CONTRACTS

**George Brencher IV, Esq.
Brenner, Saltzman & Wallman
New Haven, Connecticut**

I. Introduction

What Kinds of Contracts Are We Talking About?

As commercial use of the Internet, on-line services and electronic messaging systems continues to grow, one can imagine all sorts of business transactions being conducted in cyberspace. To an increasing degree, participants will seek to memorialize these transactions in electronic rather than the traditional paper form. Business people can gain an appreciation for many of the issues likely to be raised in such transactions by examining the application of some of the basic traditional contract principals to five types of electronic transactions: the sale of goods or services effected via Electronic Data Interchange (EDI), the on-line licensing of computer software, the provision of on-line services and the negotiation and making of more complex “negotiated” agreements. Of course, the application of the law of traditional contracts to the world of cyberspace is highly complex and uncertain. This analysis is thus necessarily somewhat oversimplified and should not be viewed as a complete discussion of all of the issues in this detailed and evolving area. Rather, it should be treated as a kind of thumbnail sketch of two principal issues raised by the specific types of transactions discussed.

II. The Basics of Contract Law

A. What is a Contract?

At its simplest, a contract is an agreement between two or more parties that the law will enforce. It is nothing more than a promise or set of promises that the law will recognize. For example, if Bob agrees with Sally that he will sell her his bicycle in exchange for \$100, and Sally agrees that she will give Bob \$100 in exchange for his bicycle, Bob and Sally have entered into a contract. Obviously, contracts can be a lot more complicated than this example, but, at bottom, they are all subject to the same basic set of legal rules. Those rules govern whether or not a contract will be enforced. That is, whether, if one party to the contract breaks his or her promise, the other party can go to court and get a judge to either order the promise breaker to keep the promise or award the aggrieved person damages for breach of the contract.

B. What Legal Rules Govern?

In general, there are two major sources of contract law: the Uniform Commercial Code (or “UCC”) and what is known as the common law. In most states (other than Louisiana), the rules of contracts are governed by the common law. The common law is the judge-made law found in legal cases. The common law of American contracts has been organized and summarized on a couple of occasions since the early part of this century and published in collections of legal rules called Restatements. The most recent Restatement of Contracts was published in 1980. When lawyers discuss general principles of contract law, they are usually talking about the law set forth in that source. Of course, because the common law is generally made by judges, the law as described in the Restatement is in a continuing state of evolution and there are always variations in the rules from state to state.

One important exception to the applicability of the Restatement of Contracts is the UCC. Article 2 of the UCC is a set of legal rules governing the sale of goods. It has been adopted (with some variations) in statutory form in every state except Louisiana. When lawyers discuss the rules of contract law as applied to the sale of goods, they are discussing the UCC (although they may not be discussing specific state variations on the UCC).

C. The Rules Governing Contract Formation: Offer and Acceptance

For a contract to be formed, the parties must reach an agreement to which they “mutually assent.” Lawyers often use the phrase “meeting of the minds” to describe the concept of “mutual assent.” That is, both parties must clearly understand each other and the subject of the agreement for a contract to exist. The process of reaching a “meeting of the minds” is most often arrived at through what are called an “offer” and an “acceptance.” In other words, one party proposes a bargain (this is the “offer”) and the other party agrees to the proposed bargain (this is the “acceptance”). For example, when Bob says to Sally: “Sally, if you give me \$200, I’ll give you this bike,” he has made an offer. When Sally says “you’ve got a deal Bob, I’ll give you \$200 for that bike” Sally has accepted Bob’s offer. Again, this example is very simple, but these same rules govern even the most complex contractual relationships. Put simply, there can be no contract unless there is an offer and an acceptance of that offer communicated to the offeree.

D. Questions Regarding Enforceability: The Statute of Frauds

There are numerous legal rules governing the circumstances under which a validly formed contract can be enforced. For example, most people are familiar with the concept that a contract must be in writing to be enforced. This is not entirely accurate, but it is a subject worth discussing in connection with electronic transactions. The idea that a contract must be in writing derives from something called the “statute of frauds.” The statute of frauds is a catch-all phrase for the ancient legal doctrine that requires most contracts to be both in writing (as opposed to oral) and signed by the parties in order to be enforceable. Modern versions of the statute of frauds are found in both the Restatement of Contracts and the UCC. The most important thing to know about the statute of frauds is that it only applies to some types of contracts, generally, those dealing with land, those dealing with goods priced at \$500 or more, and promises that, by their own terms, cannot be performed within one year. This last category of contracts is the most confusing. A

contract that, in theory, can be completed within one year is not subject to the statute of frauds. Thus, if A contracts with B to build a new Golden Gate Bridge, that contract need not be in writing because, in theory, B could complete the project within one year. However, if A contracts with B to purchase B's entire crop of Christmas trees each December for the next three years, the contract must be written to be enforceable. B cannot perform, by the express terms of the contract, within one year.

Recognizing, then, that not all contracts are subject to the requirements of the statute of frauds, the statute still has relevance for many electronic transactions. In order to understand the Statute of Frauds as it applies to on-line commerce, it is important to understand why the rule exists in the first place and how it is applied in "real world" contracting situations. The justification for the writing requirement is really two-fold. First, by putting at least their basic understandings down on paper, it was thought that the parties to a transaction would be alerted to the document's legal effect and therefore would more carefully craft their expectations yielding a more definite and clear "meeting of the minds." Second, and more importantly, by memorializing their understandings in a writing, the parties leave better evidence for a court to examine in enforcing the parties' agreement. This protects defendants from spurious claims and makes the court's job easier, thereby promoting efficiency in the enforcement of contracts.

The signing requirement has a similar foundation. First, in general, people are thought to more seriously appreciate the legal implications of a document and, as a result, to contemplate its contents if they are required to sign it. Second, it is easier to prove that a person accepted and agreed to the terms of a writing if it was signed by that person.

Finally, one further point bears discussion regarding the statute of frauds: its diminishing significance. Originally, the application of the statute of frauds was quite strict, however, courts and commentators have increasingly moved away from that strict interpretation in an effort to accommodate practical concerns. For example, the statute of frauds does not generally require all of the terms of a contract to be set forth in writing; the writing must only state the essential terms of the agreement. Further, the signature requirement has also been relaxed somewhat so that all that is required is a symbol or other means of authentication which identifies the party against whom the contract is to be enforced. This symbol may be a thumbprint, initials, a rubber stamp or an impression on paper, for example.

In applying the statute of frauds to evolving communications technologies, courts have generally been flexible and sensitive to the realities of business practices. For example, the statute of frauds has not generally been a barrier to the enforceability of contracts entered into via telegraph or telex. In telegraph cases, most courts have been willing to accept the typed paper record of the telegraphed message as sufficient to satisfy the writing requirement and have not been strict in enforcing the signature requirement. In the case of contracts entered into by telex, the paper record has not been an issue (since telex messages are transmitted in text form and automatically printed by the recipient terminal) and the signature requirement has been satisfied by the confirmation codes used in the telex transmission process. In general, a paper writing is no longer required where the parties have intentionally reduced their agreement to "tangible form".

While several cases have noted that contracts were formed via an exchange of faxes, there appears to be no reported case where the issue of the enforceability of a fax contract has been argued and decided. However, in light of the cases regarding telegraphs and telexes, it is unlikely that a court would invalidate a fax contract on statute of fraud grounds. First, the writing requirement is much more easily satisfied in the case of a fax than in the case of a telegraph since a fax is not a transcript but an exact duplicate of a writing created by the sender. Certainly there is a strong argument that the parties have

reduced their agreement to a tangible form. Second, fax signatures should be much more familiar to a court than telex codes as a reliable indication of the senders identity.

III. Electronic Contracts

A. Electronic Data Interchange (EDI).

Electronic Data Interchange, or EDI as it is often known, is one of the dominant uses of computer networking technology for commercial contracting applications today. EDI at its simplest is the movement of electronic messages, such as purchase orders, from one company's computer to another in a manner similar to the transmission of e-mail. The distinguishing characteristic of EDI is that messages are structured and coded in accordance with a standard previously agreed upon by the parties. The real benefit of EDI (and what differentiates it from e-mail) is that EDI messages can be structured so that they can be read and acted upon by the recipient's computer without the necessity of human intervention. This, of course, reduces transaction times and eliminates the risk of human error in the data entry process. EDI is an essential feature of "just in time" manufacturing systems characteristic of the automotive industry.

Of the various types of transactions examined here, EDI presents the fewest questions from the perspective of traditional contract law. One reason for this is that EDI trading partners very often agree in advance on the parameters of their trading relationship by entering into a traditional written agreement. These contracts, often referred to as "trading partner agreements" in EDI parlance, set forth the agreed upon framework for the parties' future electronic transactions such as: the message structure and code, the manner in which trade is to be conducted, the basic terms and conditions of sale, etc. Various legal organizations such as the American Bar Association (the "ABA") have published suggested model trading partner agreements of this sort. Because the parties to EDI transactions generally agree in advance on the ground rules of their contracting relationship, EDI trading often fits quite nicely into the framework of the existing contract rules regarding offer and acceptance. The parties will have agreed in advance on specific methods for communicating purchase orders (i.e., offers to buy goods or services) and for manifesting acceptance of such orders in the trading partner agreement, a traditional paper contract.

The application of the statute of frauds to EDI is perhaps less clear, but it is nonetheless unlikely that a court would refuse to enforce an EDI transaction on this basis. Generally EDI trading partners agree in their trading partner agreement upon certain record retention procedures. Indeed, record retention requirements are found in the ABA model trading partner agreement as well as in most others. This is necessary for practical, as well as legal, reasons. Because EDI transactions are often executed automatically without human intervention, the presence of a record of those transactions is necessary for audit purposes. It is probably the case that the paper printout that could be produced from EDI records would satisfy the statute of frauds requirement that the terms be reduced to a tangible form. The ABA has taken this position with respect to the record-keeping measures recommended in their model agreement. The ABA has also taken the position that EDI could satisfy the signature requirement of the statute of frauds. Because of the computer-to-computer nature of EDI, trading partners will necessarily have already taken steps to ensure message authentication. These authentication measures should qualify as symbols that sufficiently identify the sender of the message for statute of frauds purposes.

B. On-line Software Licensing.

Increasingly, software companies are using on-line registration as a method of entering into license agreements with software purchasers. Presumably, for example, Microsoft Corp. will be using such a mechanism when, as recently announced, it begins distributing its software through resellers over the Internet. This technique presents an alternative for some software makers to traditional “shrink-wrap” licenses. Indeed, an examination of some of the issues that arise with shrink-wrap licenses themselves provides insights into some of the issues arising with on-line licensing.

Historically, shrink-wrap licensing arrangements have been viewed as a practical, but potentially unreliable alternative to entering into written license agreements with software purchasers. Of course, software makers could require purchasers of software to enter into written license agreements at the point of purchase or to sign license agreements enclosed with their purchased software and mail them back to the manufacturer. But, each of these alternatives presents a variety of practical problems. Among such problems, the point of sale strategy is difficult to control since the software maker is usually not the actual seller and the mail-in agreement strategy relies upon the voluntary compliance of the purchaser. Software makers devised the shrink-wrap strategy in an attempt to avoid these and other practical issues.

The shrink-wrap licenses discussed here are those of the type which is printed on or visible from the outside of the package enclosing the floppy disc, CD or other medium on which the software is stored. Typically such packaging is sealed and bears a statement to the effect that by breaking the seal or by using the software, the purchaser has agreed to be bound by the terms of the license agreement. There are two fundamental issues that impact the enforceability of such shrink-wrap licenses, both of which can be seen in terms of our basic discussion of offer and acceptance. First, when the user purchases the software, she has never seen the terms of the license agreement. In such a case, it is not clear how she can be said to have come to a “meeting of the minds” with the software maker regarding such terms. At the time the license terms are made known to the user, she has already performed her end of the bargain in the software sale and for this reason, the user and the maker could never have agreed on the terms of the license at the time of the sale. This would be a little bit like Bob, in the earlier example, agreeing to sell Sally his bike for \$100 and then, after Sally pays him and takes the bike home, calling her and saying: “Oh, by the way, I get to use the bike on Sunday mornings.” At best, the addition of the license terms can be viewed as a later modification of the original contract between the maker and the user regarding the purchase of the software. It is difficult to argue that such terms are a part of the original contract of sale.

Second, the user’s act of accepting the additional terms set forth in the license contract is ambiguous (the breaking of a seal or the installation of the program may not be a clear enough indication of the user’s agreement to be bound by the terms of the license). Such actions are less clear signs of agreement than a signature. The ambiguousness of the purchaser’s assent is an issue of particular concern in the software licensing area. Typically software licenses are designed to do three principal things. First, they are designed to get the purchaser’s agreement not to make unauthorized copies of the software or otherwise violate the manufacturer’s intellectual property rights. As a practical matter, however, the license agreement probably does far less to protect the manufacturer in this area than the copyright law does and that protection is not at all dependent upon a contract between the purchaser and the manufacturer. Second, such contracts often are designed to limit the scope of the warranties made by the software maker regarding the performance of the product. Such warranty limitations are essential to the economic viability of software development since it is so difficult to create a “bug-free” product. Third, software license agreements also contain limitations on the liability

of the software maker for defective products, protecting them against claims for lost profits, for example. This type of limitation is also necessary to preserve the economics of the software development industry. What start-up software maker could survive if it were routinely subject to claims by purchasers of software for compensation for business down-time sparked by bugs in its software? The law, however, makes such limitations of warranty and damages difficult to enforce, especially in the consumer context. Among other things, to be enforceable these provisions must be open and conspicuous so that it is clear the purchaser will notice them. This is a way of assuring that the purchaser has clearly agreed to such terms as a part of the sale contract. The ambiguousness of the purchaser's acceptance of the contract as a whole in the shrink-wrap context may make such provisions that much more difficult to enforce.

The fact that shrink-wrap licenses are accepted via action rather than by a signature also raises statute of frauds concerns, although this may not be a significant issue since the statute of frauds does not generally apply to the sale of goods or services having a price of less than \$500. Generally, sales of more expensive software applications will be handled in traditional written form.

Finally, some have suggested that shrink-wrap licenses may be unenforceable because they are so-called "contracts of adhesion." The term "contract of adhesion" refers to standard printed form contracts which are not subject to any negotiation by the parties. In general there is a trend in consumer-oriented law to refuse to enforce such contracts where the results would be unfair. Accordingly, to the extent that they are unfair, shrink-wrap licenses may not be enforceable.

The on-line registration of software may avoid some, but not all of the uncertainties associated with shrink-wrap licensing depending upon how the transaction is structured. Assuming that the user of the software is merely registering the software on-line (as opposed to purchasing it on-line, as with the Microsoft example), the argument that the user never sees the terms of the license agreement until after the software is purchased is equally applicable in the on-line transaction as in the shrink-wrap context. Assuming, however, that the sale of the software is actually being effected on-line at the time of registration, this argument does not apply and the on-line license would not suffer from this weakness. In such a situation, the prospective purchaser can be afforded the opportunity to read the license agreement prior to paying for it. Thus, when the user pays for the program, she is clearly accepting the terms of the license as well. This argument can be strengthened if the purchaser is required as part of the transaction to signal her affirmative acceptance of the terms of the license by typing, for example, "I accept" at the bottom of the screen displaying the terms. In either case, much of the ambiguity regarding the acceptance of license terms by action rather than a signature present in shrink-wraps can be eliminated via a properly structured on-line transaction. Even where the user does not purchase the software on-line, the registration process can be structured such that the purchaser cannot use the software until the registration process is completed.¹ By keeping an electronic record of the user's registration, the software manufacturer can demonstrate acceptance of the terms of the license agreement more reliably than in the shrink-wrap context. If the sale is also being effected on-line and the user pays for the software, payment itself may be sufficient evidence of acceptance for the license to be enforceable. Again, as with shrink-wrap licenses, to the extent the license agreement contains limitations of warranties or liability, such terms should be

¹ Of course, in such a structure, the purchaser must be given an opportunity to return the software for a full refund if the terms of the license are unacceptable.

open and conspicuous so that the purchaser cannot claim they went unnoticed at the time of the sale.

With respect to the “contract of adhesion” argument, the analysis as applied to on-line licensing (or any other non-negotiated contract, whether electronic or not) is really no different than the garden variety shrink-wrap situation. To the extent that a court perceives a contract as overreaching or unfair in the consumer context, the contract may not be enforceable.

Finally, on-line registration does present one issue not raised by shrink-wrap licensing. No writing setting forth the terms of the license is produced in the on-line transaction. To the extent that the software maker can demonstrate a secure and reliable record retention procedure, it is possible that court would accept the electronic record of the registration process as a writing. However, it is unlikely that the software maker’s record retention system will be as secure as in EDI transactions, where the parties often conduct mutual audits of their records according to pre-agreed procedures and the case for a writing will likely not be as strong in this context. Moreover, in EDI the parties can always point to the traditional paper trading partner agreement as the basis for their bargain. There is no written contract to fall back on in the on-line context. That said, the willingness of courts to rely upon purely electronic records as writings is likely to increase rather than decrease as such records become more the norm rather than the exception.

C. On-line Sale of Goods

The sale of goods via electronic contracts (other than EDI) is also gaining in popularity. Such transaction are really quite similar from the point of view of contract law to the on-line registration of software where the software is also purchased on-line. The terms of purchase can readily be made available to the prospective purchaser before the contract is made and specific assent to such terms could be made a part of the structure of the transaction. In fact, in certain situations, such as the sale of hazardous goods, it may be desirable to structure the transaction such that the purchaser must review and specifically accept at least certain terms (limitations of liability and warranty for example) before the purchase can be consummated. Thus, there can be no argument that terms were added after the contract was made. If payment is made other than via an on-line mechanism, the seller may also wish to include a written copy of the sales terms in the invoice or other request for payment sent to the purchaser via ordinary mail so that when payment is made, there is a strong argument that the purchaser accepted those terms. This mechanism can also solve the statute of frauds problem by providing a traditional paper writing evidencing the terms of the agreement. But, even where payment is made electronically, a copy of the license agreement can be e-mailed to the purchaser and, if the seller keeps a detailed record of the transaction, statute of frauds problems should be no more of an issue than in the on-line registration context.

D. Provision of On-line Services

On-line service providers are moving, and should continue to move, toward using wholly electronic contracts. Those on-line service providers who enter into written agreements with their subscribers often provide pointers in their written agreements to conditions of use policies and other terms of service that appear solely in electronic form. These are not, however, electronic contracts per se and are not the focus of this discussion. Instead, the concern here is with terms of service or conditions of use that are

not backed up by a written agreement. Such electronic transactions are amenable to an analysis similar to that applicable to the on-line registration of software and the on-line purchase of goods. In contracting for services on-line, the prospective purchaser should always be encouraged to review the terms of the service agreement prior to using the services. If the service provider desires, the user can be prevented from accessing the service until she has signaled her acceptance of the terms of the service agreement and this assent can be recorded electronically by the service provider. This arrangement makes it easier to demonstrate that the user actually has accepted to the terms of service. Whether or not to require a user to view and affirmatively signal acceptance of terms of use is a decision that should be based on a balancing of the user's convenience and the service provider's desired level of certainty as to the enforceability of the terms. In a subscriber based service, payment by the subscriber for the services themselves after having had an opportunity to review the terms of service is probably a sufficient indicia of agreement. In an "open" scenario where services are provided free of charge, demonstrating assent may be more difficult (although the necessity of a binding contract with the user may be less significant as well). This situation is a common one on Web sites. So-called "web-wraps" are often employed by businesses establishing web sites for marketing purposes and these sites are generally open for browsing by anyone who accesses them. Some web-site owners attempt to protect their proprietary rights in the web site's content by adding copyright and trademark notices. Others try to limit their liability for such content. In most cases the terms relevant to such purposes however are not presented to users prior to the user accessing the site. Indeed, they are often only accessible by clicking on a link connected to a copyright notice at the very end of the home page (which may consist of several screens of material). Ordinarily, such a notice does not indicate that terms and conditions, including limitations of liability, are accessed via that link. The enforceability of such terms under current law is questionable since users may never see them let alone assent to them. It is particularly suspect where limitations of liability are involved.

Finally, unlike on-line registration, the statute of frauds generally should not be an issue regarding the provision of on-line services since the doctrine is usually not applicable to the simple provision of services.

E. Negotiated Agreements

While EDI, on-line software registration, the on-line purchase of goods and the provision of on-line services are probably the most common types of electronic contracts in use today, any type of contract could, in theory, be entered into on-line. Obviously, however, contracts which are negotiated (that is, which result from a drafting process) present more complicated issues than those which are essentially non-negotiated forms. Because of the back and forth of the negotiating process, it is extremely important that both parties agree, ultimately, on an identical document and that each can demonstrate the other's agreement to that exact document. As with EDI and other types of electronic contracts, this document can be stored in a non-paper form so long as a paper record can be produced and so long as the party seeking to enforce the contract can demonstrate the accuracy of the record. Clearly, encryption technology will be important in facilitating the creation and enforcement of these more complicated agreements on-line.

IV. Emerging Issues

A. Proposed Revision of UCC Article 2:

The National Conference of Commissioners on Uniform State Laws and the American Law Institute, the sponsors of the UCC, have been working on a number of revisions to the UCC, including to Article 2. A main thrust of these revisions is to clarify the UCC as it applies to the sale of intangible property, such as licenses to computer software. Of particular interest in connection with the issues discussed here is the proposed treatment of electronic transactions and of the statute of frauds. The proposed revisions as currently drafted specifically contemplate the enforceability of EDI transactions in particular and of electronic contracts in general. Among other things, the proposed rules would allow a contract to be formed where, after being furnished with an opportunity to review the terms of service, one party manifests acceptance of those terms by accessing or using, for example an on-line service, including, presumably, a web-site. The revisions also explicitly recognize the possibility of electronic signatures. With respect to the statute of frauds, there are competing proposals. The first is that the statute of frauds be deleted altogether and the second is that the writing requirement be carved back to require a writing sufficient only to indicate that a contract has been made which describes the subject matter of such contract. Under the latter proposal, the threshold dollar amount is to be raised to \$1,000.

Of course, it still remains for the draftspersons to settle on a final set of proposed revisions. Moreover, the UCC, as revised, will have no direct authority as a rule of law unless and until it is adopted by the states and, even then, only under the laws of those states that do adopt it. Furthermore, the UCC, as revised, would not necessarily apply to all on-line arrangements, although the sale and licensing of computer software and the furnishing of information stored in electronic media would appear to be within its scope.

B. Digital Signature Legislation

A second emerging topic of interest in connection with the law of electronic contracts is digital signature legislation. Although the statute of frauds may become less of an issue under the proposed revisions to the UCC, it will remain desirable in a variety of contexts, including with respect to contracts not covered by the UCC, if electronic

transactions are considered “signed.” In the last year at least two states, Wyoming and Utah, have enacted specific legislation bearing on this issue. The Wyoming law was specifically designed to make it possible to file documents electronically with the government of that state. Under the new law, the Wyoming secretary of state is empowered to identify a procedure or procedures by which such filings may be authenticated and the choice of that procedure is left undefined. The Wyoming law is significant simply because it adds credence to the general view that digital signature technology is reliable enough to satisfy legal signature requirements. It does not specifically address contracts between private parties. The Utah law, by contrast, applies to a wide variety of electronic contracts and messages, including those with the Utah state government. In its legislation, Utah also adopted a particular digital signature technology(public key encryption) as its choice for authentication. The Utah statute is very significant because it flatly states that a digitally signed document is as valid as if it had been on paper. While there are those who are critical of the Utah legislature’s choice to favor public key encryption over other potential methods of encryption or over other methods of satisfying the signature requirement in electronic commerce, there can be no doubt that the existence of this new law lends further strength to the argument that electronic transactions can be structured so as to satisfy traditional requirements of contract law.

LEGAL ASPECTS OF USING E-MAIL

**George Brencher IV, Esq.
Brenner, Saltzman & Wallman
New Haven, Connecticut**

Introduction

The use of electronic mail as a routine internal and external communications medium is becoming increasingly common both among lawyers and among business people. The practical advantages of e-mail are obvious, it is in many instances a faster and more effective communications tool than many of the alternatives. E-mail can be sent at any time and, depending upon the configuration of the e-mail system, from virtually anywhere. It does not rely upon the effectiveness of human messengers and doesn't have the space limitations of voice mail. E-mail does, however, bring with it a variety of concerns that are often overlooked by company and law firm managers intrigued by this new and accessible technological "fix." Two such concerns are particularly significant. First, the content of e-mail messages is discoverable in litigation and, second, the use of e-mail can pose issues of security. None of the concerns raised by e-mail, including the discoverability and security issues, however, is so insurmountable as to render e-mail unusable for most purposes and there are some relatively simple and painless ways to overcome each of them.

Use of E-Mail in Litigation

Perhaps the most significant potential issue involving e-mail is one which may go unappreciated by many lawyers and non-lawyers alike: e-mail is "discoverable" in litigation. In other words, e-mail messages, like all other forms of communication, may be used as evidence in a lawsuit both by the author and by the opposing party. Indeed, it would appear that discovery of electronic records, including e-mail, is a current hot topic among litigators. Moreover, e-mail messages need not have been reduced to writing in order to qualify as discoverable documents. The electronic record of the e-mail message itself can be the source of the discoverable material. Indeed, even e-mail messages that were "deleted" by the recipient can, depending upon the configuration of the e-mail system in question, be retrieved from the back-up storage media. This was a relatively well-publicized technique used several years ago by investigators looking into the Iran-Contra matter. However, its use is no longer limited to exotic cases involving issues of national security. Today, such retrieval may be compulsory under court rules governing discovery applicable to ordinary litigants. Certainly this makes e-mail a potentially more significant source of discoverable material than oral communications. Unlike telephone conversations, for example, e-mail, especially where there is an electronic back-up, outlasts the span of human recollection much like paper records do. Because of the retrievability of deleted or erased e-mail messages, e-mail may even outlast its paper counterparts. This is especially true where paper records are subject to a regular document destruction policy (although the creation of paper documentation using electronic means such as word processing and spreadsheet applications, files poses problems with similar to those relating to e-mail in terms of retrievability of back-ups).

While discoverability of e-mail in litigation is not a unique aspect of this communications medium, the fact that e-mail is subject to compulsory production in a

lawsuit may, and perhaps should, affect the way in which businesses make use of e-mail. Because of its accessibility and ease of use, e-mail seems to users like a less formal means of communication than traditional written documents. Users tend to treat e-mail much more like the telephone than the typewriter. Thus, e-mail messages are very often far less formal than written communication ever would be. One writer has even likened e-mail to the 90's version of the office water cooler(a lively forum for all manner of office socializing.

While this fact in and of itself is not necessarily a bad thing(informal communication is often appropriate and efficient(users of e-mail should bear in mind that their messages could one day be subject to public view and interpretation in a court of law. Failing to appreciate this aspect of e-mail could have results which are at best embarrassing and at worst potentially harmful to a company. One anecdote that appeared in the New York Law Journal serves to prove this point. According to this account, e-mail messages were used as evidence in a \$150 million securities fraud lawsuit brought by Siemens Corp. against the Atlantic Ritchfield Corporation ("ARCO") arising out of the purchase by Siemens of an ARCO subsidiary. E-mail apparently retrieved from the ARCO subsidiary computer system purported to show that employees of the subsidiary were aware of significant problems with one of that company's principal products which were not disclosed to Siemens at the time of the sale. One of the messages allegedly authored by an ARCO official at the time of the transaction reportedly states that "the whole basis of our plan is almost invalid due to the fact that we have been operating under the wrong assumptions for 10 years." Needless to say, a message such as this could prove highly damaging in litigation, as could many messages that crop up in the virtual water cooler scenario. Office gossip can be fertile ground for employment lawyers, for example, bringing discrimination, harassment or wrongful discharge claims.

Security

The second significant issue regarding the use of e-mail is security. E-mail, like other communications media, is often used by businesses to transmit messages containing sensitive or confidential information. The disclosure of some of such information, for example, trade secrets or other confidential or proprietary information, could be embarrassing or harmful to a business. The failure to take proper precautions against the disclosure of trade secrets alone can jeopardize their status as such. Many users, however, fail to appreciate the potential security risks associated with the use of e-mail. Depending upon the type of e-mail system used, users of e-mail are subject to varying degrees of risk that the content of such messages could be intercepted by unauthorized third parties without the knowledge of either the sender or the recipient.

Before discussing the risks posed by different e-mail systems, however, one important aspect of the security of e-mail bears mentioning: the Electronic Communications Privacy Act of 1986 or "ECPA", a federal statute codified at 18 U.S.C. §2510 et seq. The ECPA is the principal law governing eavesdropping, wiretapping or other interceptions of communications. While the ECPA is a complex and wide-ranging statute, of particular importance here are some aspects of its treatment of e-mail. The ECPA regulates access to and the interception of electronic communications, including e-mail, making it a crime (and, in most cases, a felony), to do any of the following:

to intercept an electronic communication;

to disclose or use the contents of an electronic communication which you know have reason to know was unlawfully intercepted; or
to access, without authorization, an electronic communications facility; or
to intentionally breach an authorization to access an electronic communications facility and to thereby obtain unauthorized access to electronic communications

These restrictions are subject to a number of exceptions, including provisions for access by law enforcement officials and, under certain circumstances, by the provider of the communications service and for e-mail messages that are readily accessible to the general public, such as postings to computer bulletin board systems. Access and disclosure is also allowed with the consent of the sender or the recipient. By making the interception and use of e-mail a crime, the ECPA was intended to provide a measure of privacy to the users of e-mail and to promote its use as a communications medium. The effects of the ECPA on the security of e-mail are difficult to gauge, however, at least in part because unauthorized access to electronic communications can be difficult to detect. Moreover, the fact that eavesdropping on e-mail is illegal does not necessarily mean that such eavesdropping does not occur.

There are numerous systems available for conducting e-mail communications, including direct modem-to-modem links; in-house routing systems, servers and bulletin boards; third-party services such as America On-Line, CompuServe or MCI Mail; and the Internet. Each presents varying degrees of security. With modem-to-modem links and in-house systems, users control the security of their own communication system and are free to implement whatever controls they feel are appropriate. In general, these systems can be configured to offer a high degree of security. For most users of e-mail, however, particularly those exchanging messages with third parties, such as customers or suppliers, e-mail communications are handled either by a third-party service or over the Internet.

Of the latter two, third-party services offer the highest degree of security. First, the ECPA does not restrict a service provider or its employees from accessing and disclosing messages with the consent of either the sender or the recipient. Some service providers include such a consent in their subscription agreement or terms of service. Businesses making use of such services should review their agreements and may wish to negotiate to have such a provision removed. They may also wish to consult with prospective recipients of their e-mail, at least where it is anticipated that confidential material will comprise a large volume of the messages to such a recipient or where particularly sensitive information may be involved. Even where consent has not been obtained, the primary threat to the security of e-mail sent over third-party services (other than the misappropriation of the user's password and ID number, a risk shared in common with most other e-mail messaging systems) is access to such messages by employees of the service provider where consent is not required. Under the ECPA, a service provider may lawfully access "stored" communications, for example e-mail messages that are in a user's mailbox awaiting delivery, at any time and without notice to either the sender or the recipient. Disclosure of such communications, as opposed to access, however, is only lawful in three principal situations: first, where the user has consented to such disclosure; second, at the insistence of law enforcement authorities; and third, if the service provider believes the communications pertain to the commission of a crime. Thus, absent consent, in most situations even if the service provider does access a company's e-mail, it may not lawfully disclose its contents. As a practical matter, most of the major third-party services claim, contractually or otherwise, not to

allow their employees to access the private e-mail of their users (other than in situations where issues of system security or unlawful activity are involved) and the use of a well-known and established provider should suffice to allay concerns of service party employee eavesdropping. This is especially true if the service provider represents to the user in its terms of service or otherwise that it will not access user's stored e-mail.

While use of the Internet for e-mail purposes is subject to the same risks as those posed by third-party services, it is subject to one additional risk not shared with other systems. Because e-mail sent over the Internet is often routed through a series of computer systems as it makes its way to the recipient and because the sender has no real control over the route the message takes, e-mail messages sent over the Internet are subject to a greater risk of interception. Unfortunately, the sender of e-mail over the Internet cannot satisfy its security concerns simply by investigating its Internet access provider and assessing the provider's reliability. While the provider's system may be secure and its personnel reliable, the sender's mail will pass through any number of unknown and unknowable organizations' systems before it reaches its intended destination. Of course, in most instances, interception of such a message would violate the ECPA, but since such interceptions are difficult to detect, it is not clear how much of a deterrent the ECPA presents. Moreover, there is some potential for interception and disclosure of the user's message where such conduct would not violate the ECPA since that statute does not apply to inadvertent or unintentional actions. Finally, if the e-mail message is sent abroad, the ECPA will offer no protection since that statute's scope is limited to conduct within the United States. Thus, the use of the Internet for e-mail presents the greatest security risk of all of the messaging system options.

Other Concerns Involving E-Mail

Although the potential discoverability of electronic messages and risks of security breaches are two of the most significant issues raised by e-mail, there are a number of other concerns which bear mentioning here. One such concern is sexual harassment conducted over e-mail. In one reported account, an employee was said to have sent a co-worker some 67 sexually explicit messages and propositions over the company e-mail system during a ten-day period. Although sexually harassing messages could be communicated via traditional non-electronic means, it is arguable that e-mail facilitated the communication of such a large volume of messages in such a short period of time without attracting attention from supervisors and co-workers. Perhaps a more significant threat than one-on-one harassment, though, is the ability of a single employee to harass a large number of victims with a single message. One instance of this conduct reportedly occurred when a large number of employees of Chevron were sent pornographic material via e-mail by another Chevron employee. The employees attempted to bring a class action lawsuit alleging sexual harassment. Chevron reportedly settled the suit for upwards of \$2 million.

Another concern is the posting of e-mail on Internet newsgroups. Such postings may bear a company return address or other indicia of their origin that suggest the content of the posting is endorsed in one way or another by the company. Obviously, organizations will want to control the content of whatever public statements they make, whether posted to a newsgroup or disseminated through any other media and managers should be concerned about the possibility of employees making or appearing to make unauthorized statements in this manner.

A third source of concern is the dissemination of copyrighted material via the company's e-mail system. If the organization has Internet access, this issue may be further complicated by an employee downloading proprietary material using the company's computer system. In such cases, businesses face the prospect of vicarious or even contributory liability under the copyright laws. While the law is in a state of flux in this area, the potential exposure could be quite significant.

Finally, companies may be concerned that their e-mail systems will be used for the theft of trade secrets. One well-publicized pair of cases illustrating this issue is currently making its way through the state of California legal system. The cases, one civil and one criminal, involve a former employee of Borland International Co. who, prior to joining Symantec Corp., allegedly communicated trade secrets belonging to Borland to Symantec's CEO.

Formulating an E-mail Policy

The potential for e-mail to be used in litigation, the potential for the interception and disclosure of e-mail messages and the variety of other concerns raised here, while serious issues, need not deter companies from making use of this efficient tool for communication. Rather, once these potential issues are appreciated, measures can be taken to minimize the likelihood of future problems in these areas. Such measures can take the form of an enterprise-wide e-mail policy. Some of the features of such a policy are set forth below:

Emphasize to all users that the company's e-mail system is the property of the company and that it is intended solely for the purpose of carrying on company business.

Personal messages on the company e-mail system are among the most likely to contain informal remarks that could prove damaging if produced in litigation. Company gossip, for example, could be introduced in the context of a lawsuit over the termination of an employee. Avoid this problem by discouraging the use of the system for such purposes.

Advise users that all e-mail messages should be business-like and professional. Although they need not be as formal as written letters or memoranda, users should refrain from using inappropriate, vulgar, profane or harassing language.

The purpose of this guideline is to formalize somewhat the content of the user's messages without rendering e-mail the functional equivalent of formal written communication. While ease of use and speed may be among e-mail's greatest strengths, highly informal messages can be damaging.

Incorporate the company's e-mail system into its ordinary record retention procedures so that e-mail is archived and/or destroyed in a systematic manner. Measures may also need to be taken to prevent deleted or erased e-mail from lingering on the computer system or back-up storage media.

A company should know, as with paper records, which electronic messages it has retained and which it has not. This facilitates the orderly production of and analysis of material in preparation for litigation and can help to avoid the potentially damaging discovery of previously unknown evidence in the course of litigation.

Incorporate the Company's use of e-mail into its overall policies regarding the treatment of confidential information. Users should be made aware that information transmitted via e-mail may be subject to security risks and that security measure may be appropriate in some cases.

Users should be told not to leave e-mail messages on their screens when their desk is unattended and to change their passwords regularly to avoid unauthorized access. Moreover, the use of encryption technology may be advisable if there will be extensive use of e-mail, especially over the Internet, containing trade secrets or other sensitive information.

Particularly if you have Internet access, advise users that the e-mail system should not be used for the uploading, downloading or printing of copyrighted materials (including software) in violation of the copyright laws.

This guideline can help to insulate companies from the allegation that they willingly or knowingly facilitated a violation of the copyright laws.

Once an e-mail policy is formulated, it must be clearly communicated to users of the e-mail system in advance of the users engaging in e-mail communication. Businesses may wish to incorporate the policy into existing employee manuals or may wish to have users sign a receipt indicating their acknowledgment and agreement to its terms. The utility of having such a policy is seriously undermined if users are unfamiliar with its terms or worse—unaware of its existence. Text notes appearing on the access screen to the e-mail system itself referring to the policy may be a useful way to remind users that their access to, and use of, the system is subject to a specific set of rules. A well formulated e-mail policy incorporating the above guidelines which is clearly communicated to users in advance should assist companies to avoid some of the areas of concern associated with the use of e-mail.

Of course, even the most well-drafted e-mail policy, like the ECPA, cannot shield e-mail users from all potential pitfalls associated with this new communications medium, but they can help prevent such problems from arising.

Monitoring User's E-Mail

The question of whether to monitor user's e-mail naturally flows from an appreciation of some of the risks associated with the use of e-mail and the process of

formulating a company policy regarding such use. Whether or not e-mail is to be monitored at all is a complicated issue of company policy that calls for a careful balancing of a variety of interests and considerations. Indeed, the propriety of employer monitoring of e-mail is a hotly debated topic within the business, legal and political communities and companies have adopted a wide range of positions on this issue. Some have opted for a policy stating that user's e-mail will be subject to regular monitoring in the ordinary course of business. Others have opted not to regularly monitor messages, except in response to legal process, obligations to third parties or as a part of a specific investigation. One point on which there appears to be near universal agreement among commentators, however, is that businesses should both make an affirmative decision on what their policy is regarding the monitoring of employee e-mail and they should clearly communicate it to their employees. Failure to do so may leave users of the system with incorrect impressions of the degree of privacy they enjoy in their e-mail communications and such incorrect impressions could expose the business and its managers to potential claims based on an invasion of privacy in the event e-mail is accessed without prior notice.

In making a determination whether to monitor user e-mail as a matter of policy, employers need to know the scope of their right to access such communications under current law. Unfortunately, the law in this area, like many others involving cyberspace, is in a state of flux. Accordingly, while some general guidance can be given on this subject, companies are urged to consult with legal counsel prior to establishing a policy and to keep abreast of developments which may affect the policy they have ultimately settled upon.

The starting point for any analysis of the legality of accessing user e-mail in the employer-employee context is the ECPA. In general, the ECPA does not prohibit employers from accessing employee e-mail. There are four specific justifications for this view which may be relied upon by the employer. First, the employer may have the consent of the employee (the ECPA does not place any restrictions on access to, and dissemination of, electronic communications with consent. Consent of the employee could either be in the form of an express written consent form signed by the employee (for example, where such consent is part of the company's e-mail policy signed by all users) or it could, arguably, be implied if employer access to the employee's e-mail is a condition of the employee's continued employment. Obviously implied consent is a less certain position to rely upon. Second, businesses who operate the e-mail systems used by their employees (as opposed to using third-party providers such as CompuServe or MCI Mail) may rely on the exceptions found in the ECPA applicable to service providers. In general, this would allow companies to freely access all "stored" communications such as e-mail residing in employee's mailboxes. A third basis for employer access is the so-called "business-extension exception." The ECPA does not regulate the interception of electronic communications using devices furnished by the employer and used in the ordinary course of business, such as telephone calls to an employee's office extension. This exception may also extend to communications to and from the employee's desktop computer, such as e-mail, however, the parameters of the "business-extension exception" are, as yet, quite uncertain and employers should use caution in relying on this ground for the wholesale monitoring of employee e-mail. Moreover, this exception would not extend to e-mail messages sent from an employee's home computer (at least where that computer was not provided by the company). A final ground is the fact that, at bottom, a business has the right to access data which is, by definition, its property. This would include all business correspondence and files created by an employee in the course of her duties. Where electronic communications consist of information which is proprietary to the employer, the employer probably has the right to access such communications. This

determination, however, calls for a case-by-case determination and thus may be undesirable as a basis for an employee e-mail monitoring policy. In general, employers will be able to rely upon at least one of these four grounds to support their right to access employee e-mail without liability under the ECPA. Aside from the ECPA, there appears to be no other federal law that would bar companies from monitoring employee e-mail. Although there have been some recent efforts at introducing federal legislation aimed at reducing such access, these do not appear to be gaining momentum in light of the new Republican majority in Congress.¹

There are some state laws, however, that may create privacy rights in employee's e-mail which may restrict an employer from monitoring such communications. These laws include state wiretapping statutes which may be more restrictive regarding the interception of electronic communication than the ECPA. They also include state tort law which may allow for a claim based upon the common law actions of intrusion from seclusion or publication of private facts (two traditional bases for claims of invasion of privacy). The application of state law to this area is uncertain for a variety of reasons. Tort law claims for invasion of privacy, for example, generally require the plaintiff to establish as part of her legal case that she had a reasonable expectation of privacy in the matter disclosed. If an employer has adequately informed its employees of its policy of monitoring e-mail, it may be able to defeat such a claim on this basis. If an employee has expressly consented to such monitoring, the argument for an expectation of privacy in such messages should be weak. Moreover, it is arguable that state law statutes and common law claims in this area are preempted by federal law in the form of the ECPA. Further, the application of state law in some instances may raise complex questions of jurisdiction where the message sender, the intended recipient, the message router and the employer may be located in multiple states. Finally, there is significant variation in the law from one state to another. Accordingly, issues of state law should be carefully reviewed with the assistance of legal counsel before a user monitoring policy is implemented.

Addendum: Some E-Mail Issues for Lawyers

The security issues surrounding e-mail pose special issues for lawyers who make use of this communications tool. Under both the Model Rules of Professional Conduct (see Rule 1.6)) and the Model Code of Professional Responsibility (see Canon 4), an attorney has a professional responsibility to preserve information communicated to the attorney by the client in the course of legal representation. Given that attorney communications containing client confidences carried out over e-mail are subject to a risk of interception and disclosure, it is not inconceivable that the use of un-encrypted e-mail for such purposes could be viewed as an impermissible breach of the attorney's ethical duties. Indeed, similar issues have been raised about the use by lawyers of cellular and cordless telephones, and at least one bar group, the Committee on Professional and Judicial Ethics of The Association of the Bar of the City of New York, has recommended that lawyers exercise caution when making use of such communications media. In this connection it should be noted that cellular telephone communications and the radio

¹ One such statute, The Privacy for Consumers and Workers Act, sponsored by Senator Paul Simon of Illinois, has reportedly been withdrawn from consideration at this time. Simon has announced that he will not be seeking re-election to the Senate when his term expires in 1996.

portion of cordless telephone transmissions are also protected from interception and disclosure under the ECPA. In other words, notwithstanding the fact that it is unlawful to eavesdrop on attorney communications made over cellular and cordless telephones, an attorney may be subject to allegations of unprofessional conduct based upon his or her use of such devices.

The potential for interception and disclosure of e-mail also raises questions regarding the attorney-client privilege, a rule of evidence which cloaks communications between an attorney and her client in which one has a reasonable expectation of privacy. The presence of third parties who may overhear the communications ordinarily is sufficient to defeat the privilege. Again, in the cellular and cordless telephone area, some courts have held that no reasonable expectation of privacy exists in such communications due to their susceptibility to interception, while the state of California recently amended its code of evidence to provide that attorney client communication is not deemed lacking in confidentiality solely because such communication was conducted over a cellular or cordless telephone. Obviously, the law on this question, even as regards cellular phones, is unsettled. Based on these developments, however, it is at least arguable that attorney client e-mail communications, especially where they are not encrypted, are not protected by the attorney client privilege. The argument, of course, is even stronger if those communications are un-encrypted, since encryption lowers the risk of interception and thereby makes it more likely that legally recognized privacy interests exist in such communications.

Accordingly, it may be incumbent upon attorneys communicating client confidences via e-mail to take advantage of readily available encryption technologies. The failure to do so could be deemed a waiver of the attorney client privilege or it could form the basis of allegations of professional misconduct. At the very least, un-encrypted communication should be limited to less sensitive matters.

Finally, as a closing comment in this area, it should be noted that lawyers are not unique in that they are subject to a professional duty to maintain information confidential. Medical professionals, such as doctors and therapists, and financial professionals, such as accountants, are subject to similar restrictions and may be subject to similar legal exposure in the event of inappropriate disclosure of confidential information. It may also be advisable for such professionals to avail themselves of encryption technology to avoid potential allegations of misconduct.

Launching Content Into Cyberspace

**An Introduction to
Information Commerce
Security Technologies**

**Internet World
Electronic Publishing Resources**

Digital Content

n When Digital Information is the Product

- Electronic Publishing
- Business Information
- Interactive Multimedia
- Computer Software
- Entertainment

n Multiple Delivery Vehicles

- Internet
- CD-ROM
- Cable, Broadcast, Satellite TV
- Private Networks, Dialup
- *Combinations*

Information Commerce

n Digital Content, PLUS:

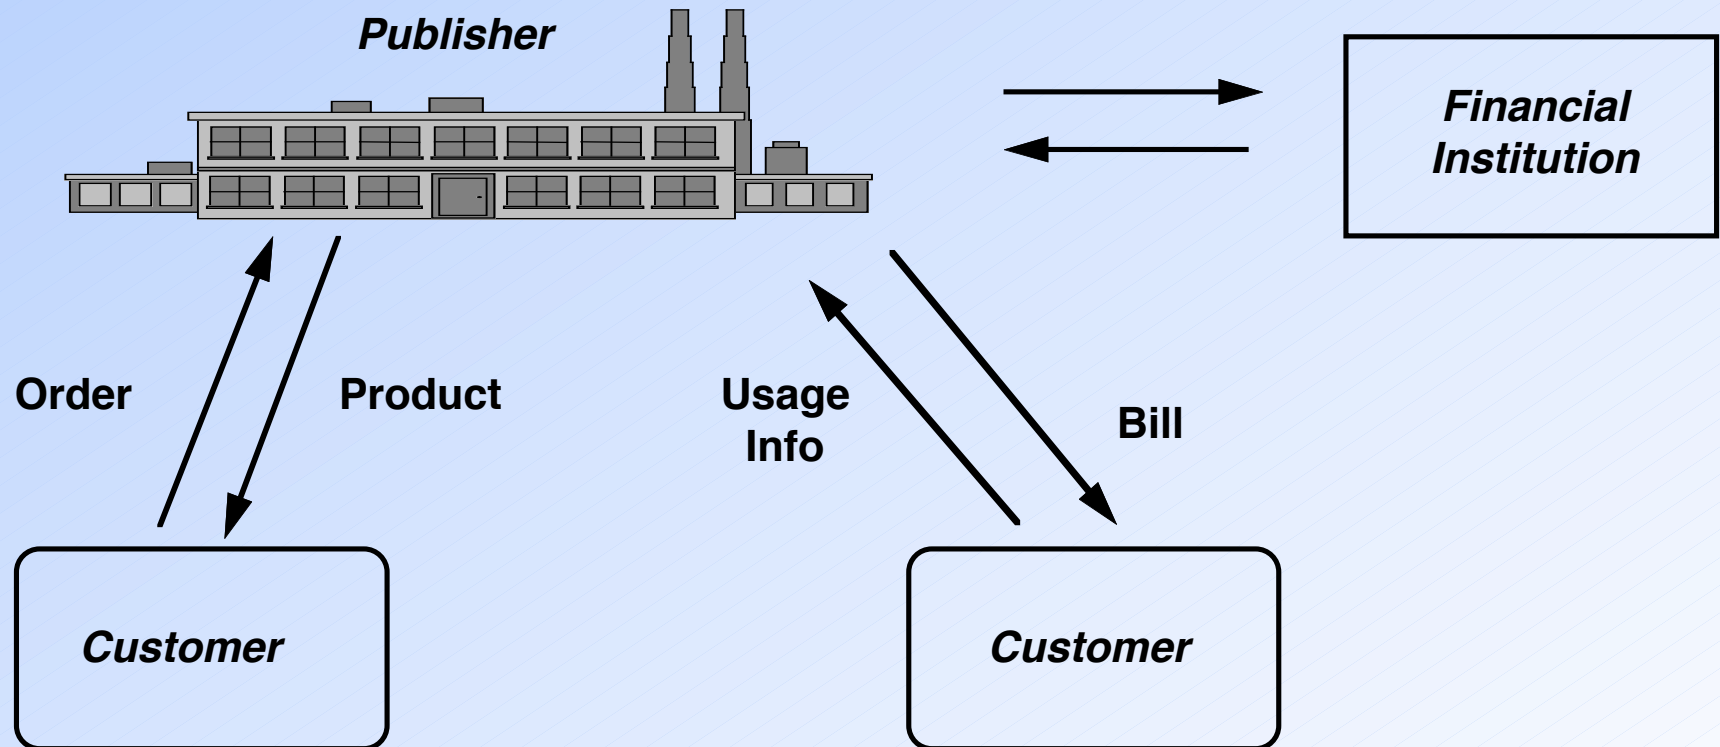

- Electronic Payment Methods
- Value Chains based on Multi-Party Transactions
- “Back Channels” of Marketing/Usage Information

n Info-Commerce Requires:

- Protection of Copyrights and Licensed Uses for Properties Launched into Cyberspace
- Getting Paid - Efficiently - for Micro-Transactions
- Collecting Usage Information
- Ensuring Advertising
- Support for Traditional and New Publishing Models

Current Publishing Model

All Transactions and Control go through Central Publishers, Clearinghouses, Financial Institutions - Information Moves Physically

Today's Information Commerce

- n **Bulk Distribution, Bulk Payment**
 - Newspaper *Subscription* as an Example
- n **Rights Enforcement by Contractual, Legal Agreements**
 - Only Physical Disincentives to Violation
- n **After-the-fact Compensation, Reporting to Value Chain**

Today's Protection Models

n **Lock/Unlock, or License Manage, the Content**

- Various Systems Deployed Today
- Once Unlocked or Use-allowed, Content is Unprotected
- No Pay-By-Use or Usage Data Collection with Lock/Unlock
- License Management Schemes Require LAN Configuration with Local License Server and are Not Particularly Secure

n **“Protect the Wire” Schemes**

- SHTTP, SSL from Netscape, NetScape (WWW only)
- Secures the Transmission of Content to User and Payments, Information back to Clearinghouse
- Content and Information are “Released” into the Clear at Both Ends, Leaving Rightsholders and Users Unprotected

Today's Protection Models, cont.

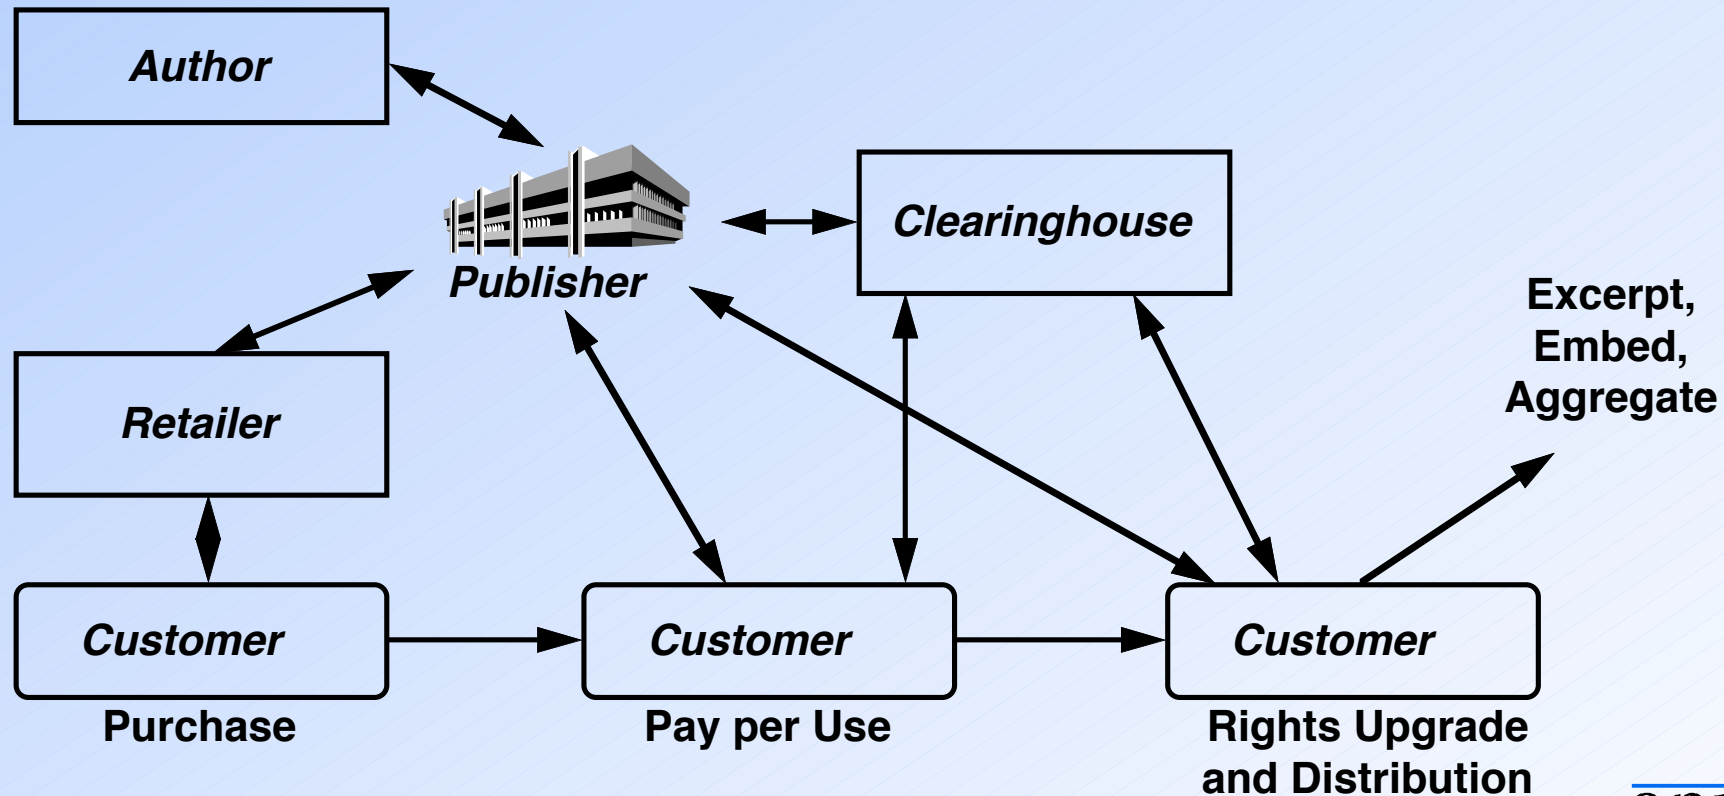

n Early Metering

- Wave, InfoSafe, CD-MAX
- Provide for Limited Pay-By-Use and Usage Data
- Typically Require Hardware-based Security
- Specific Clearinghouse and Business Model Topologies

n No General-Purpose, Multi-Party Value Chains

New Electronic Publishing Model

Direct and Value Chains for Delivery of Products, Including Customer to Customer; Secure Preservation/Transmission of Usage, Rights, Billing

Electronic Information Commerce

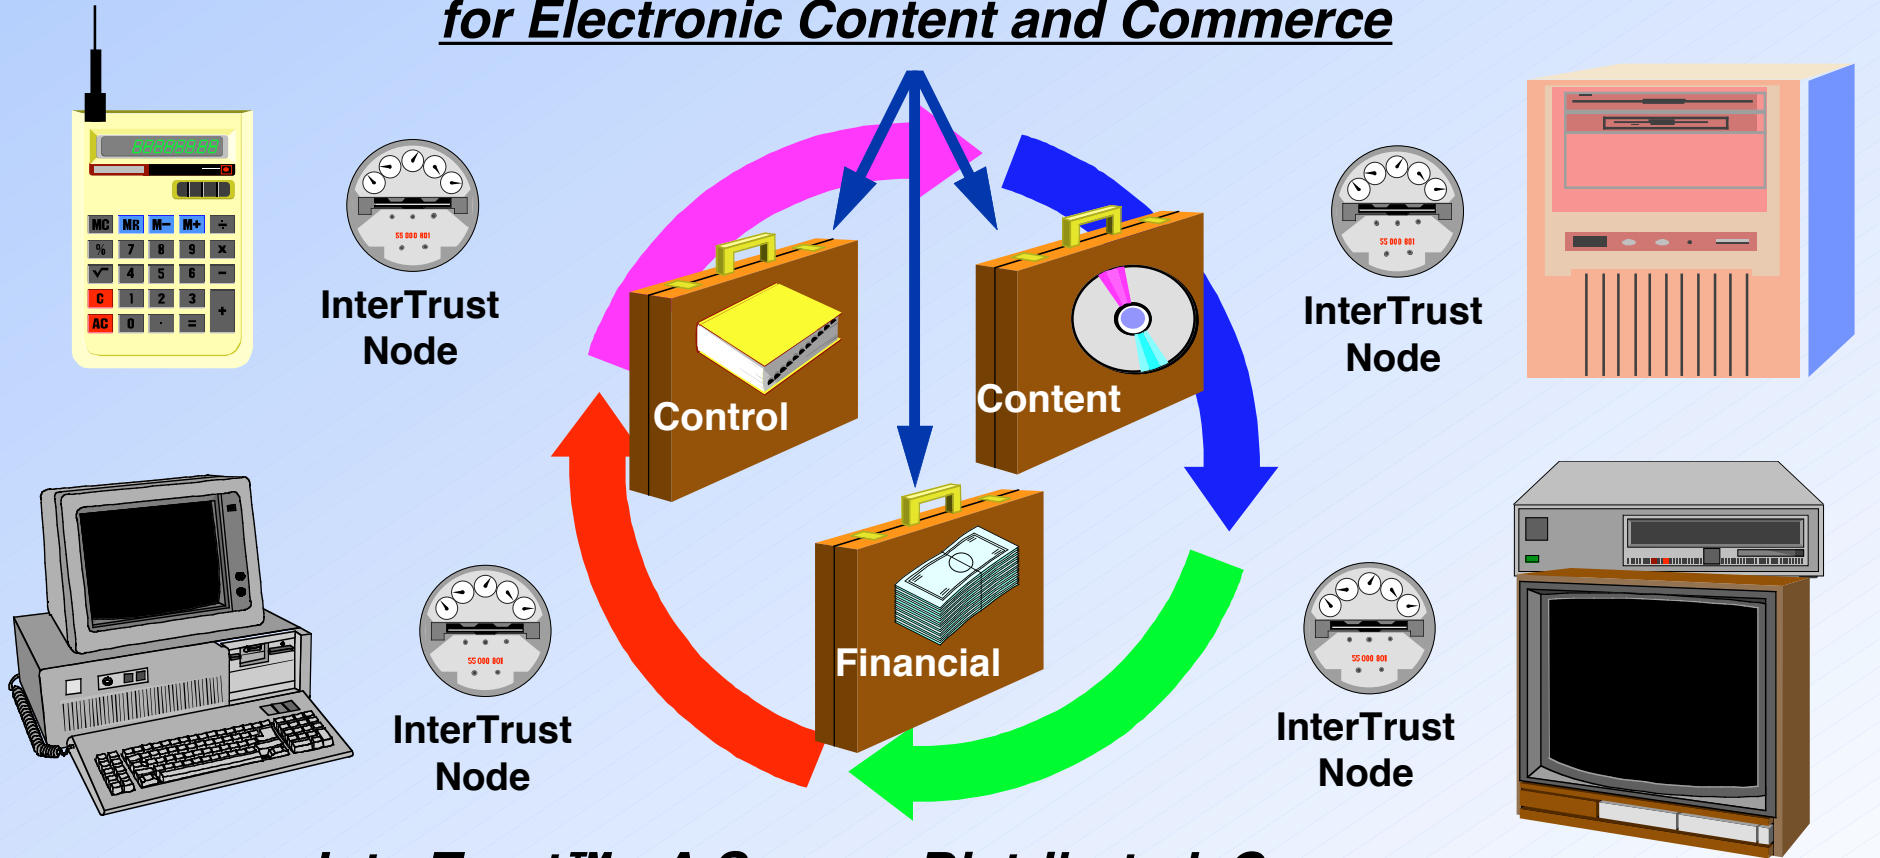

- n **Targeted Distribution, Micropayments**
 - Newspaper **Article** as an Example
- n **Rights Enforcement by Computer System**
 - Cryptography, Security Mechanisms
- n **Implicit Compensation and Reporting**
- n **New Business Models**
 - Package (Containers)
 - Transport Information Securely
 - Use A Variety of Paths

Distributed Rights Protection

- n EPR DigiBox and InterTrust**
- n Package All Information in the System (Content, Control, Financial) in Containers along with Rules and Controls for Use**
- n Provide Distributed, Multi-Party, Tamper Resistant, Object Oriented, Generalized, Rights Protection & Transaction Processing Environments**

Rights Protection at Work

DigiBox™ : A Universal Container for Electronic Content and Commerce

InterTrust™ : A Secure, Distributed, Commerce Infrastructure

What are DigiBox & InterTrust?

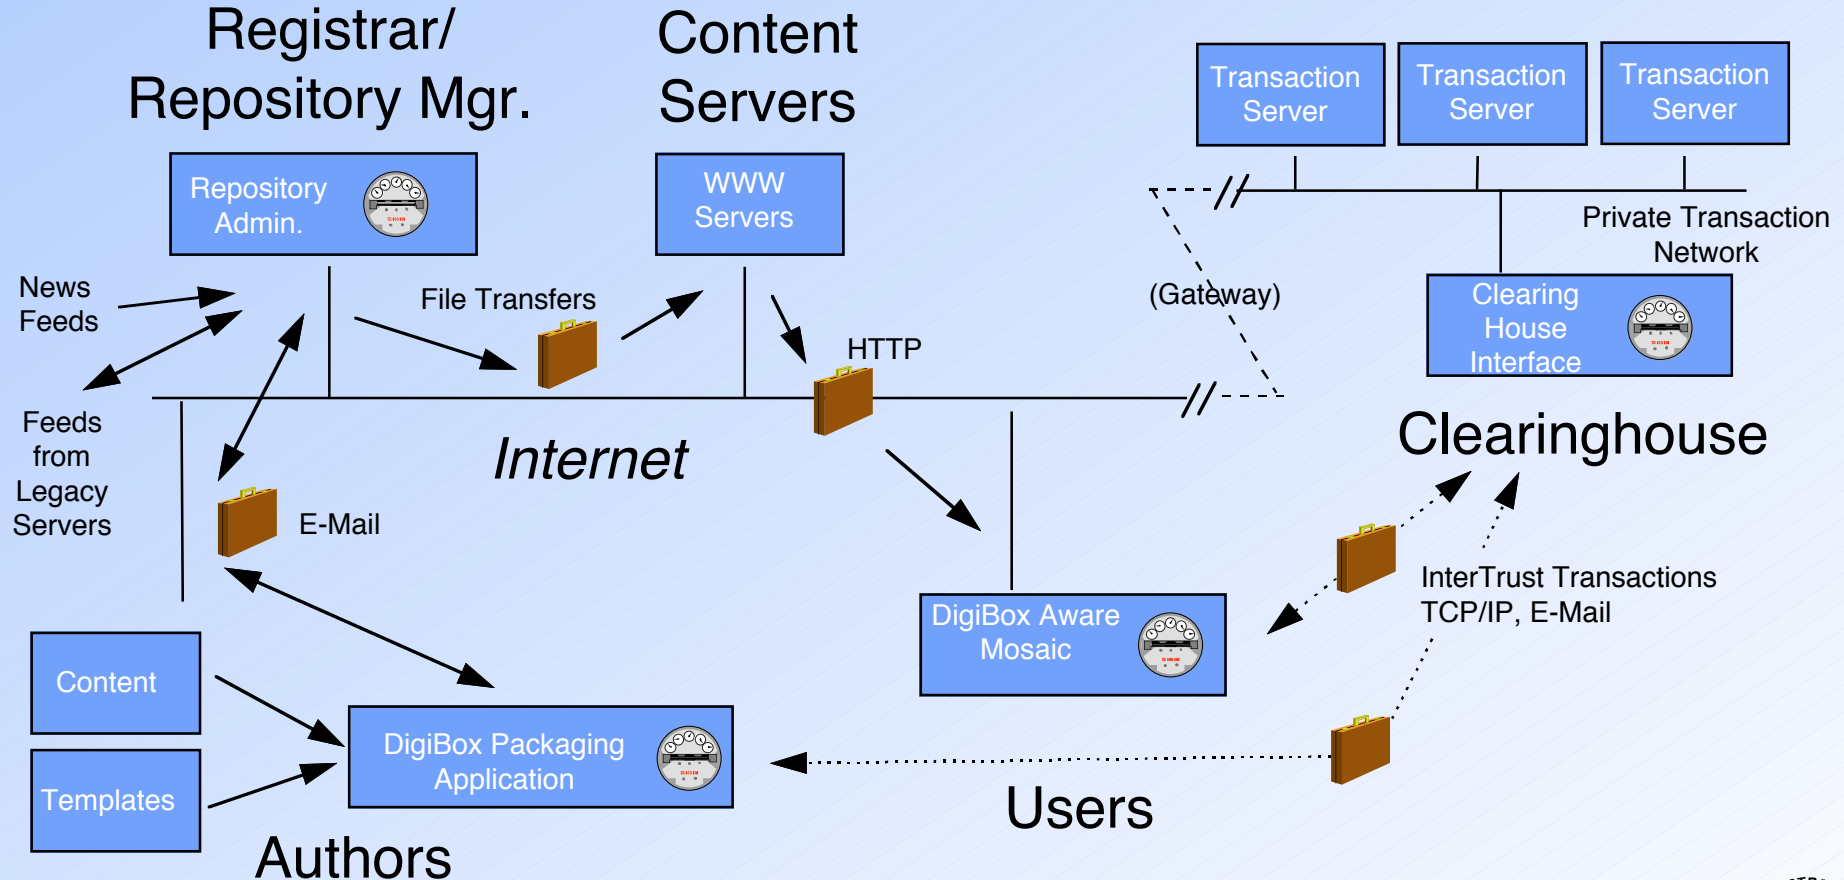

n DigiBox: *A Universal Container for Electronic Content and Commerce*

- Content: Video, Multimedia, Graphics, Text, Software, etc
- Financial: Transaction Information and Credit/Digital Cash
- Control: Content Rights, Permissioning, Administration

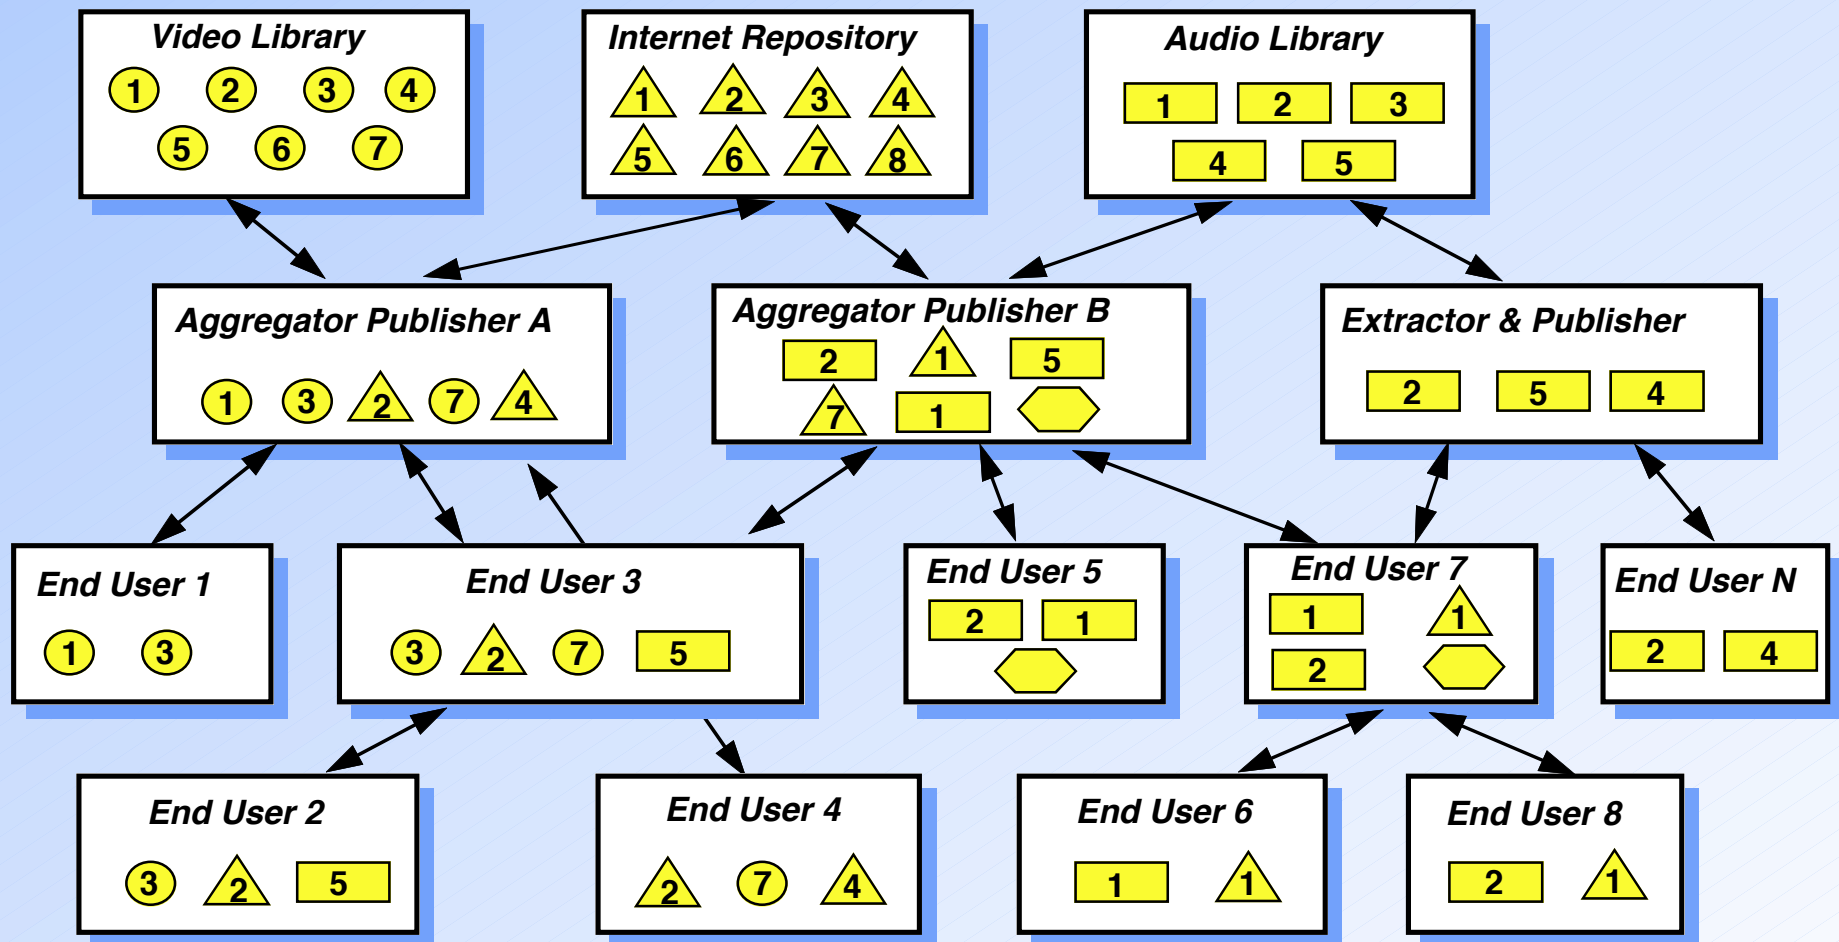

n InterTrust: *A Secure, Distributed Commerce Infrastructure for DigiBox Content & Applications*

- Computers and Other Electronic Appliances
- Running InterTrust Software on Distributed Nodes
- Employs Broadcast, Networks, and/or Media interchange

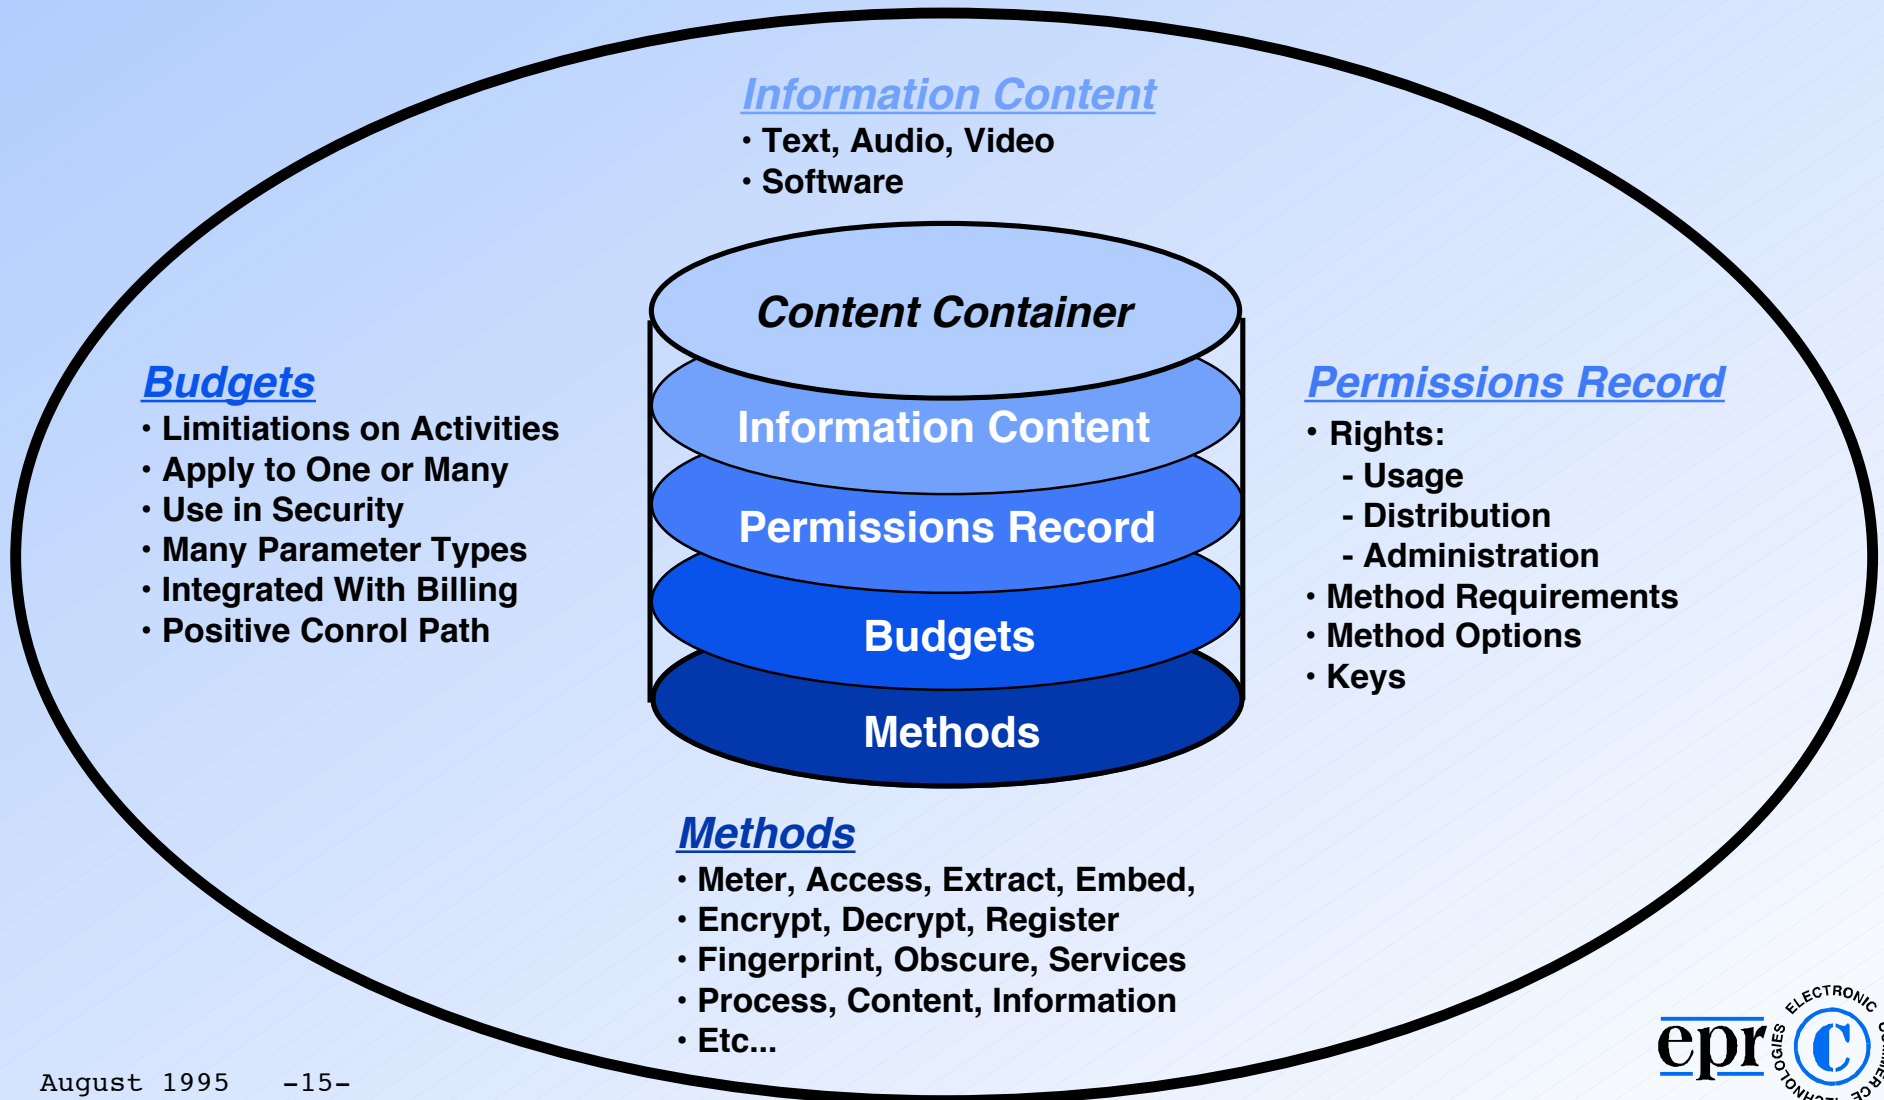

InterTrust / Internet Example

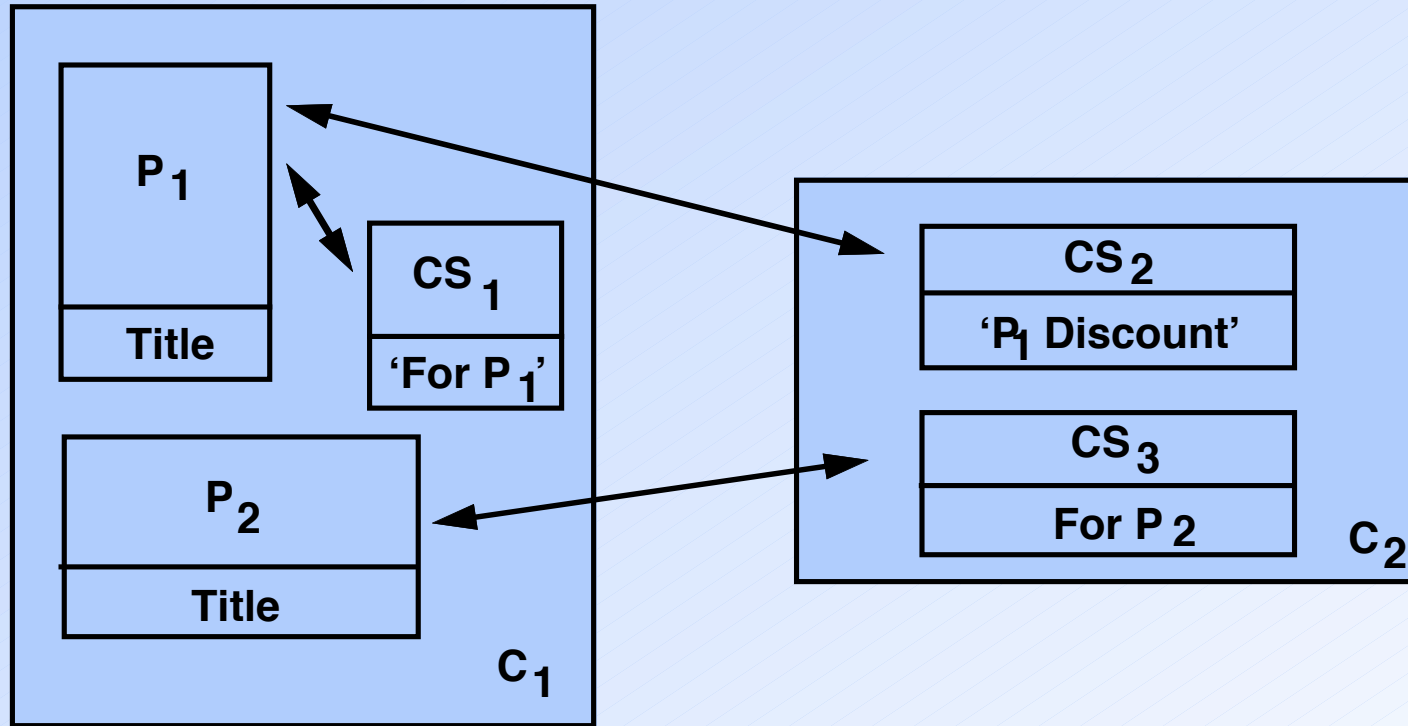

Superdistribution: Chain of Handling & Control

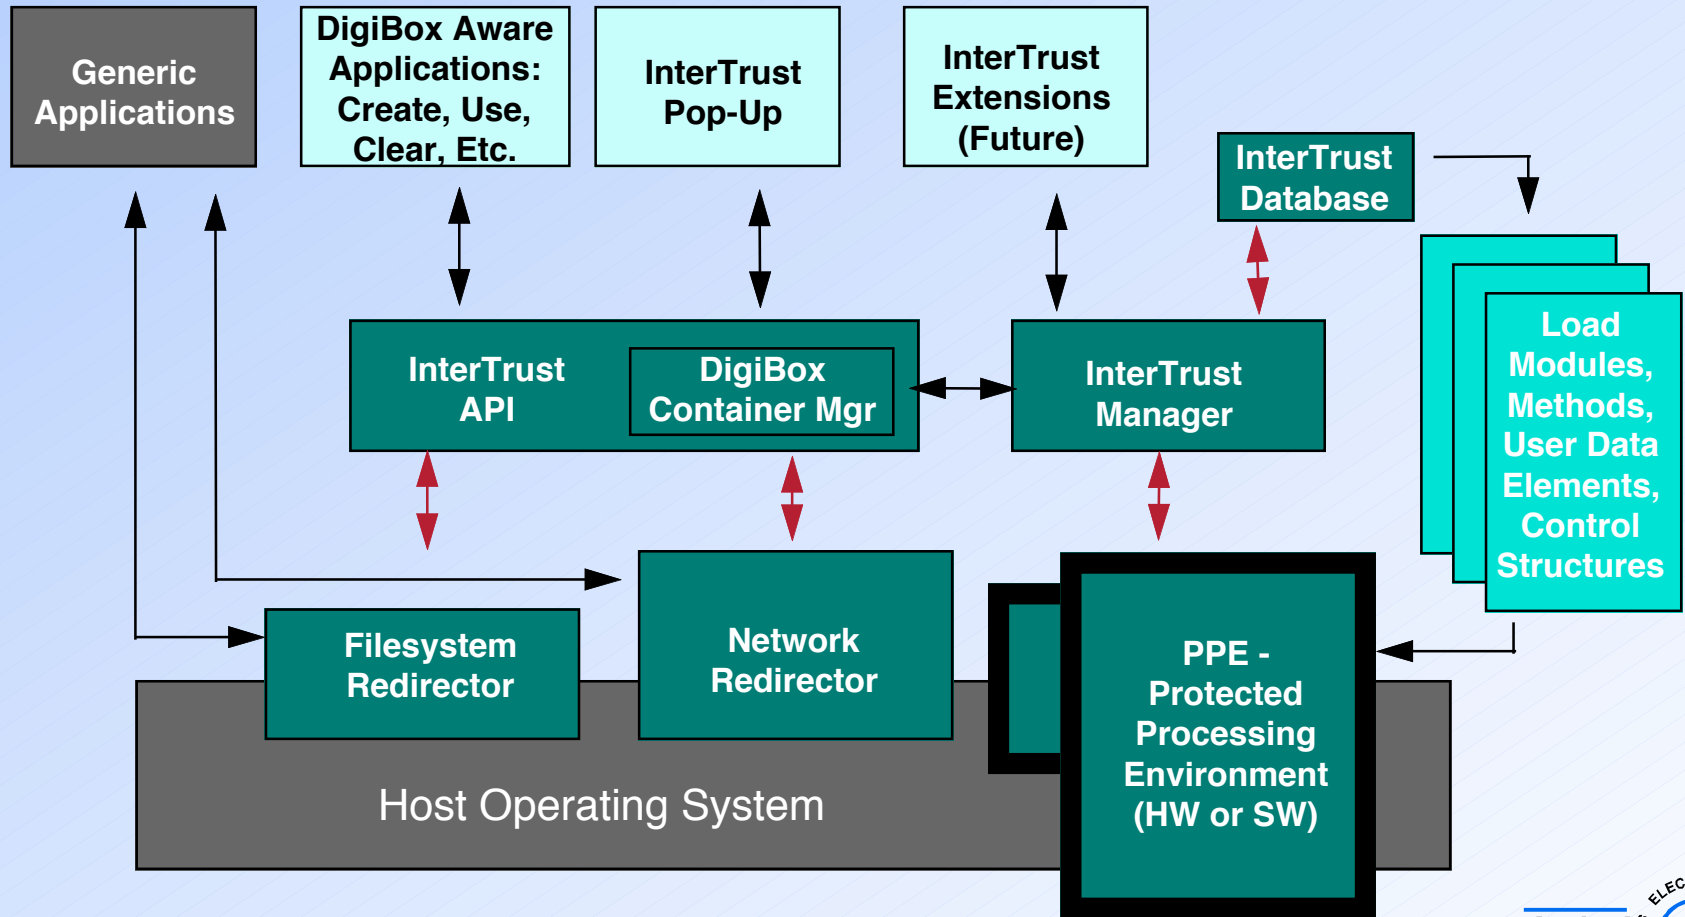

DigiBox Container Structure

Container Logical Organization

InterTrust Protected Processing Environment

Breakthrough Technology

- n **True Chain of Handling & Control = Superdistribution**
- n **Secure Transactions Inside each InterTrust Node**
 - Can be Securely integrated into the Host Operating System
 - Can Employ Secure Hardware Integrated w/the Host
- n **Secure Engine Packages & Processes:**
 - Data Objects (Text, Recordings, Movies, Pictures, Trusted Messaging, Electronic Cash, Credit, Transfers)
 - Control Objects (Rights, Permissions, Price)
- n **This Unique Approach enables implementation of**
 - *Any Number of Commerce Models*
 - *With Any Number of Participants*

Enabling Superdistribution

Electronic Data
Interchange,
Legacy
Connectivity

Security and
Cryptography
Techniques

Electronic
Funds
Transfer,
Banking,
Financial
Centric

Content
Centric
Digital Rights
Info Metering

End to End
Applications w/
Built-in
Electronic
Commerce

Infrastructure
Technologies

EDI

Crypto

EFT

Content

Service

Network

DigiBox

InterTrust

Applications & Users

- n Internet, WWW
- n Software Licensing
- n Digital Cash
- n Information Databases
- n Video on Demand
- n Electronic Shopping
- n E-mail
- n Electronic Advertising
- n Micro Marketing Info Collection
- n Games
- n System Software Providers
- n Computer, Info-Appliance Providers
- n Content Distributors, Aggregators, Creators
- n Common Carriers
- n Cable, Movie, Recording
- n Large Corporations, Government Agencies
- n Chip Makers

Conclusions

n Information Commerce Systems Must:

- Protect ALL the Information in ALL the Transactions
- Support Multiple, Evolving Business Models and Real World Value Chains
- Support Multi-Party, Superdistribution Topologies

n Next Steps:

- Standardize a Neutral Content and Commerce Container
- Proliferate a General Purpose Processing Environment
- Create an Information Commerce Infrastructure with Options for Packaging Tools, Delivery Vehicles, and Clearinghouses

Internet World - Boston

Tim Duncan

CorpFiNet

How Do You Get An
Internet Related
Business Worth \$10
Million By 1996?

CorpFiNet - The Internet Finance Network

- Commercial and Corporate Finance on the Internet.
- Information for Business Finance Professionals.
- Content Directory.
- Original Information and Articles.
- Transactions.
- Consulting, Web Site Development and Management, Strategic Partnerships for Financial Service Companies.

CorpFiNet Objectives

- Attract a Target Audience in a Specific Vertical Business Market.
- Learn About What the Audience Wants.
- Help Clients Sell to the Audience.
- Help Clients Transact Business.

Points for Content Providers:

- Start-Ups Still Require Time and Capital.
- Revenue Generation Today From Education & Know-How.
- Revenue Generation Tomorrow From Delivering Business.
- This is an Information Business not Entertainment.
- Information is the “Toaster” of Tomorrow.

How Do You Get An

International Commerce

International Aspects of Internetting

Czeslaw Jan Grycz

Grycz@Poniecki.Haas.Berkeley.edu

Background

What Right Do I Have to Talk About This?

- ✓ Publisher, lecturer, writer, consultant -1965-present
- ✓ DLA Office of the President, UC - 1989-1994 (Retired in 1994)
- ✓ Prototyped large-scale e-publishing projects
- ✓ Co-authored *The New Riders' Official Internet Yellow Pages*
- ✓ Director, **Wladyslaw Poniecki Charitable Foundation, Inc.**, international networking and publishing
- ✓ V.P., **Santa Fe Ventures, Inc.**, PBS program and network productions, www consulting, integrated media
- ✓ Burned fingers and involved in enriching experiences

What will be Covered

Setting the Stage for Laura Fillmore

- ✓ I. Internetting Issues
 - ➡ Components of international Internetting
- ✓ II. Case Study
 - ➡ An example from Central and Eastern Europe
- ✓ III. Conclusions and Recommendations
 - ➡ Is there profit in getting involved?

I INTERNETTING ISSUES

What's involved in
Internationalization?

Components of International Internetting

1. You extend the Internet into new territories
2. You're involved in practical implementation of consensus decision-making
3. Living example of democratic governance
4. Provide mechanisms for free speech
5. Build online communities and strengthen existing ones
6. You can develop business potential

1. You extend the Internet (its ideals and its challenges)

- ✓ World's largest communication enterprise ever-known; defies easy definition
- ✓ Bi-directional communication (interactivity)
- ✓ “Access” is the first key to understanding the Internet; “listening” is the second
- ✓ Dynamics have geo-political implications; we don't yet adequately understand these

2. You Demonstrate Consensus Decision-Making

- ✓ Internet has no governing body, *per se*
- ✓ Lots of contributing entities
- ✓ Problem-solving with a variety of experts
- ✓ Local involvement generates commitment
- ✓ You need to build confidence in your partners
- ✓ Leadership is as important as ever
- ✓ Watch local standards, copyright, censorship

3. You implement Democractic Governance

- ✓ Important to provide leadership with respect for individual differences (personal, cultural, national)
- ✓ Variety of skillsets necessary
- ✓ Absence of real collaborative tools
- ✓ Legislative vs. local controls
- ✓ Backwardness of a “broadcast” mentality

4. Providing Mechanisms for Free-speech

- ✓ Some countries resist Internet expansion
- ✓ Requires a variety of points of access
 - * Governmental
 - * Institutional (higher ed, mainly)
 - * NGO
 - * Public / Individual
- ✓ Mentoring on the Internet

5. Building Communities and strengthening existing ones

- ✓ What is the right analogy? 30,000,000 users? - or - 1,000,000 groups of 30 interested participants?
- ✓ Networking and collaborative tools far behind job control, remote access, and individual communications ones
- ✓ The problem of “Globalization” in Strengthening Local Communities

6. Developing Businesses

- ✓ New ground rules by which to play...
 - * Win-Win
 - * Based on open information systems/processes
 - * Need for non-profit citizen/industry coalitions
 - * Increase in joint ventures/joint profit sharing
 - * Environmentally sensitive
 - * Whose is the market?

II

Case History

The Environmental Training Project's
“EcoDirectory of Central and
Eastern European Environmental
Libraries”

The “EcoDirectory” Project

- ✓ US-Agency for International Development
(UMinn, UPitts Center for Hazardous Materials Research, Institute for Sustainable Communities, World Wildlife Foundation; Sub-Contractor: Poniecki Foundation)
- ✓ Collaborative Library Project
- ✓ Learn while doing; Internet/Eco-Directory
- ✓ Establishing sustainable bodies: IOIS
- ✓ Creative newness: ILS proposal ==>>>>>>>

Lessons from the Library Project

- ✓ Technology - Infrastructure
- ✓ People - Preparedness and commitment
- ✓ Language - Communications
- ✓ Culture - Behavior
- ✓ Publishing - Content *is* the value
- ✓ Legislation - Policy issues *are* critical
- ✓ Commerce - Doing business

Policy Issues

- ✓ Team and Internet (community) developed
- ✓ Ease of use
(range of participant knowledge)
- ✓ Critical mass (availability of resources)
- ✓ Extensibility (applicable elsewhere)
- ✓ Reciprocity
(the provider will also become a customer)

Indicators of Quality on the Internet

- ✓ Recognition by one's peers (or grateful audience; or response of marketplace)
- ✓ Publisher acceptance (Imprint)
- ✓ "Seal of Approval" (Society Endorsement)
- ✓ Evaluation process (Peer Review)
- ✓ Respected individual authority (Mentoring)

Building Sustainable Communities

- ✓ Emerging from the “EcoDirectory” Project... the idea of a membership-driven, multi-disciplinary association in Central and Eastern Europe... with potential expansion to other sites: IOIS.

International Organization of Information Specialists (IOIS)

- ✓ International scope and outreach (CEE)
- ✓ \$\$\$ help provide training, translations, travel, meetings, pilot projects
- ✓ Membership-driven
- ✓ Exporting successful models and adapting them locally
- ✓ \$50./yr - U.S. dues

International Organization of Information Specialists [IOIS]

c/o

Wladyslaw Poniecki Charitable Foundation, Inc.

8637 Arbor Drive

El Cerrito, CA 94530-2728

Grycz@Poniecki.Haas.Berkeley.edu

The next Stage

An unexpected development

- ✓ From the “EcoDirectory” and the initial “IOIS” meetings, came the realization of a need for a new kind of school: to train information managers for the 21st Century: the emergence of the International Library School project.

International Library School

Training Managers of Digital Libraries for the 21st Century

- ✓ Torun, Poland
(birthplace of Nicholas Copernicus)
- ✓ Postgraduate degrees: courses, utilizing distance ed., local lectures, Internet, internships
- ✓ Students from East as well as West
- ✓ Faculty, technology, software, and founding partners are all needed...

International Library School

Training Managers of Digital Libraries for the 21st Century

c/o

Wladyslaw Poniecki Charitable Foundation, Inc.

8637 Arbor Drive

El Cerrito, CA 94530-2728

Grycz@Poniecki.Haas.Berkeley.edu

International Internetting Truisms

- ✓ The true value of the Internet is in its bi-directional flow of information...
- ✓ What information you decide to publish on the Internet is as important as the information you retrieve...
- ✓ Service and support will generate loyalty and sales...

III

Conclusions, Predictions and Recommendations

Conclusions

Why You Should Become Involved

- ✓ **Ethical:** Responsibility of those ...
“...to whom much has been given...”
- ✓ **Social:** Surest way towards evolving a positive human presence on this earth (peace)
- ✓ **Cultural:** World populations are individually gifted; possess unique and critical values
- ✓ **Economic:** Business opportunities abound in both directions

Predictions

- ✓ Internet will be recognized in 2020 as most effective tool of disseminating democratic free-market philosophies
- ✓ Pure capitalism will not be allowed to dominate, online communities will preserve the intrinsic social value of the Internet experiment
- ✓ Businesses will have integrated Internetting

Recommendations

- ✓ Focus on **Service** for an initial international Internetting effort
- ✓ Learn to seek out and value cultural differences
- ✓ Join IOIS to help others help themselves (develop local preparadness)
- ✓ Participate in the International Library School (teach, financial support, internships)

Enjoy!

October 31, 1995 -- updated 11:55 a.m. EST (1655 GMT)

Canada stays united but ...

Quebec vote is 'a wake up call'

October 31, 1995

Quebec separatists who wanted their Canadian province to become an independent country almost pulled it off, an indication to both separatists and federalists that a future split is still possible. By daylight Tuesday, Montreal police reported calm after overnight clashes, looting and arson that followed announcement of the final vote tally -- 50.6 percent "no" and 49.4 percent "yes."

Predictions From the Past . . .

"Housekeeping is such a simple matter when ordering is done over the wires. A morning's tiresome shopping can be done in 10 minutes, in the comfort of one's own boudoir. There is so much more time left for pleasure and recreation and things that are worthwhile."

Telephone Company Ad
Philadelphia, 1905

... and Forewarnings:

"We are getting perilously near the ideal of the modern Utopian, when life is to consist of sitting in armchairs and pressing a button. It is not a desireable prospect; we shall have no wants, no ambition, no youth, no desires, no individuality, no names and nothing wise about us."

British Journal , 1892

Secure Communication and Commerce over the Internet

Amir Herzberg

Network Security Group

IBM – T. J. Watson Research Center

amir@watson.ibm.com

URL: <http://www.research.ibm.com/watson-netsec>

Network Security Group Directions:

- Internet Security
- Electronic-Commerce
- Secure Mobility (mobile-IP, CDPD, RF-LAN...)
- Cryptography and provable security
- Proactive Security (security recovers from break-in into servers, with proactive help from unbroken servers - attacker must break all/many servers together)

IBM Research

Agenda

- Secure Communication across the Internet
 - What is the right layer?
 - Applications of IP layer security
 - Requirements for IP layer key management
 - High level design
 - Status
- Security for Electronic Commerce
 - Secure Payments - Model, Requirements
 - Proposals
 - SEPP - Secure Electronic Payments Protocol
 - Status
- Conclustions

IBM Research

Internet Security

WHAT IS THE RIGHT LAYER?

** NEED FOR STANDARD!*

Secure Communication Across Internet

- Secure IP tunnel over insecure Internet.
- Implement, establish Internet standards (IP-SEC WG)
- Session key distribution and refresh; data encryption, authentication, integrity.
- Allows public key or key distribution center (e.g. DCE, NetSP).
- Secure party-to-party communication
- Private virtual network over Internet
- Open, Secure, Efficient.

IBM Research

- . IP secure tunnel over insecure Internet
- . Firewall-to-Firewall, Firewall-to-mobile, Firewall-to-Home
- . session key distribution, data encryption, authentication
- . Packet filtering at firewalls to block intruders.

IP Key Management Requirements

- Efficiency, Simplicity, Versatility, Scalability, Minimize Licensing
- High Security:
 - Trustworthy, conservative design
 - Modularity: replace broken pieces, allow tradeoffs / upgrades
 - Recovery from key exposure (by cryptanalysis or break-in) \Rightarrow forward secrecy, proactive security
 - Protect against denial of service (detect, prevent 'clogging')
 - Anonymity

IBM Research

High Level Design

1. Anti-clogging defense: exchange 'cookies' (random numbers appended to all messages to identify source)
2. Key Sharing: use public keys (RSA) and cookie to authenticate a key
3. Authenticated Key Exchange (DH) for forward secrecy, proactive security
4. Key Refresh (against cryptoanalysis; detect denial of service)

IBM Research

Status

- Proposed standard for packet encryption/authentication
- Key management: still converging... maybe 1H96?
- Good performance
- IBM available product: NetSP secure gateway
- Other interoperable products (from multiple vendors) coming

IBM Research

Secure Electronic Commerce

- Internet as marketplace for electronic commerce.
- Security is a major concern.
- Secure payments - a critical enabler.
- Our goals:
 - Open market, standards, inter-operability.
 - Migration: allow gradual acceptance.
 - Long term - rich functionality.
 - Short term: Keep It Simple; 20/80 rule.
- Focus on charge cards: simple, common, extend existing system.

IBM Research

Electronic Payment Systems (partial list)

- General security schemes (SSL, SHTTP, secure E-mail, secure IP) - secure communication only, trust merchant, no non-repudiation.
- Non-cryptographic (First Virtual) - trust e-mail 'callback loop' and limit exposure
- Anonymous cash (DigiCash, CAFE) - more complex, impact on financial process, legal issues.
- Shared key crypto (SNPP, NetCheque, NetBill) - requires acquirer to cardholder relationship
- Public key crypto (STT, SEPP, iKP, CyberCash, Secure Courier)

IBM Research

Secure Electronic Payment

SEPP vs. iKP

- SEPP uses 3KP (with minimal modifications)
- SEPP extends the iKP spec (e.g. certificates and implementation details)
- SEPP represents agreement on interoperable implementations among NetScape, CyberCash, GTE and IBM
- SEPP would be submitted to IETF (as soon as I-D formatting done)

IBM Research

SEPP vs. STT (my personal opinion)

- Very similar goals and approach. Differences mainly due to design process: closed for STT vs. open for SEPP (IETF, WWWC, four vendors...)
- SEPP uses standards: ASN.1, X.509v3, ISO 8583, MIME
- Security: SEPP widely reviewed (esp. the core protocol - iKP); some concerns for STT
- SEPP is more efficient (4 vs 10 'hard' ops)
- STT requires licensing: RC4 and MS
- SEPP is web and e-mail, STT only e-mail
- SEPP contains enough details to implement.

IBM Research

SEPP vs STT in short...

- Similar.
- Close vs open process.
- Standards
- Interoperability, 'devil in details'
- Efficiency
- Security
- Scope of spec

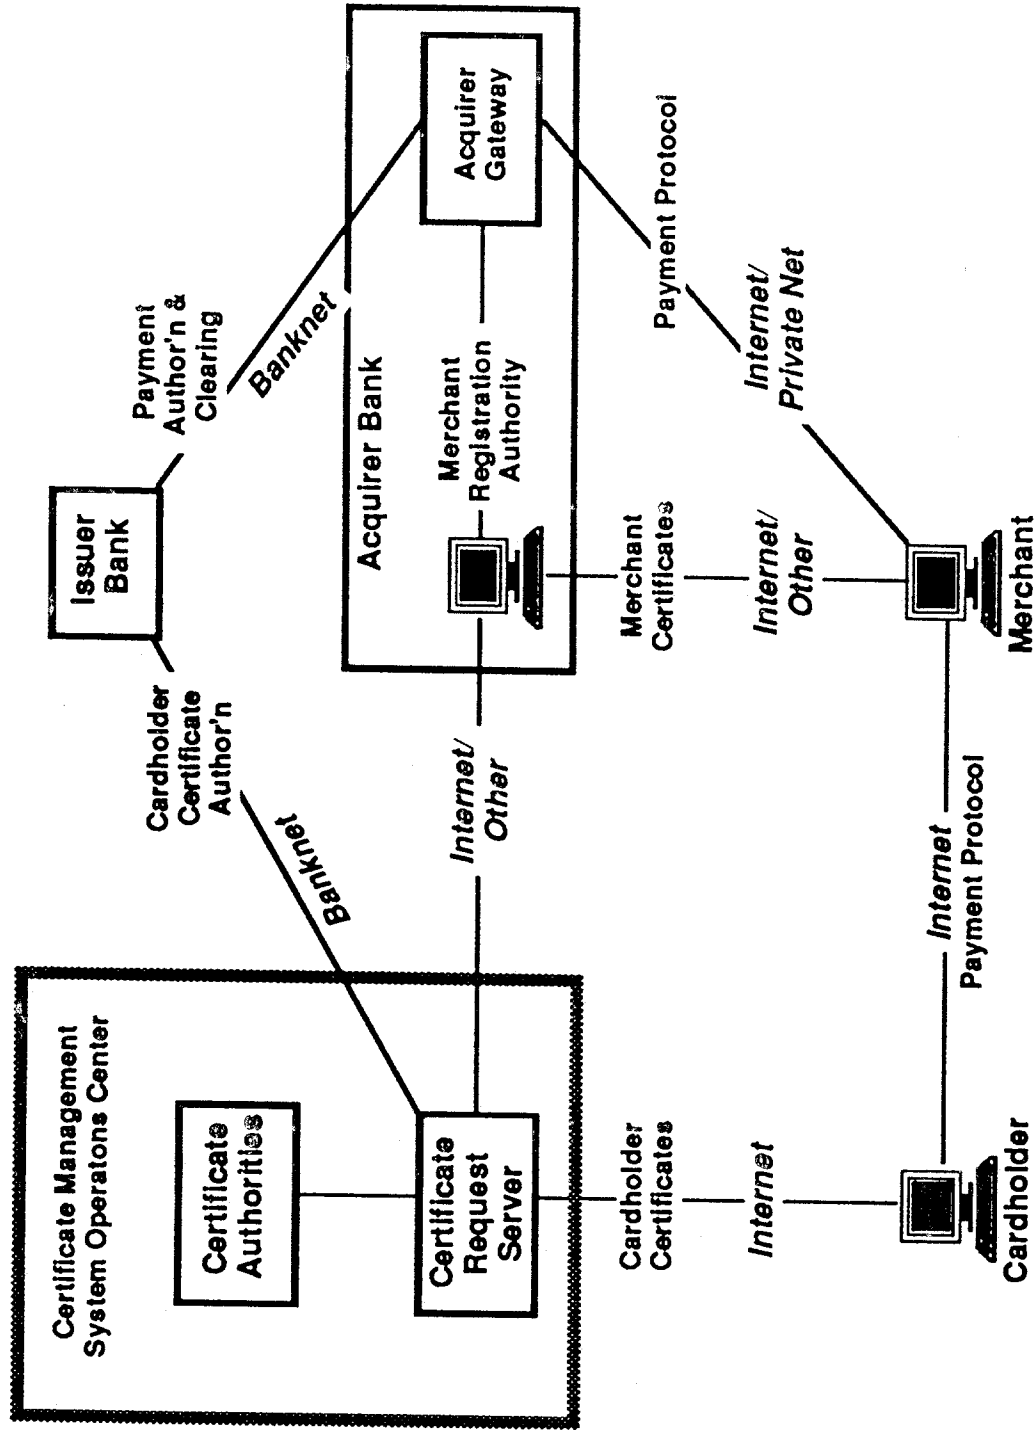

IBM Research

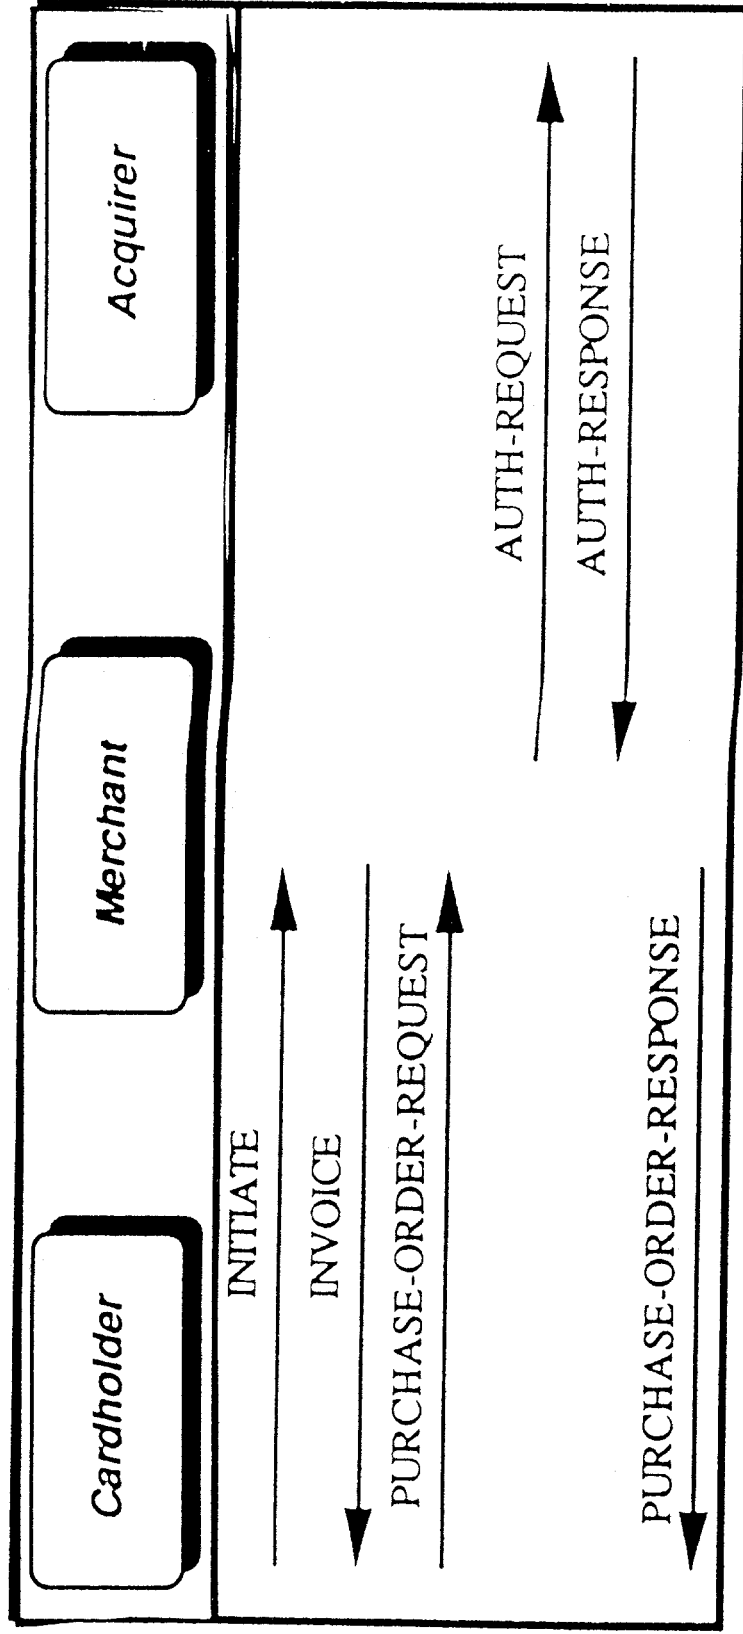

Elements of SEPP

- Payment protocol
- Certificate issuing and management
- Implementation over WWW and e-mail
- Interface to financial networks
- Error handling and disaster recovery

DRAFT - VERSION 1.1
Secure Electronic Payment Protocol

This is the basic purchase order message flow. The merchant may choose to perform "inline" authorization, as shown here, or delay authorization until some later time

Offline Purchase Order Flow

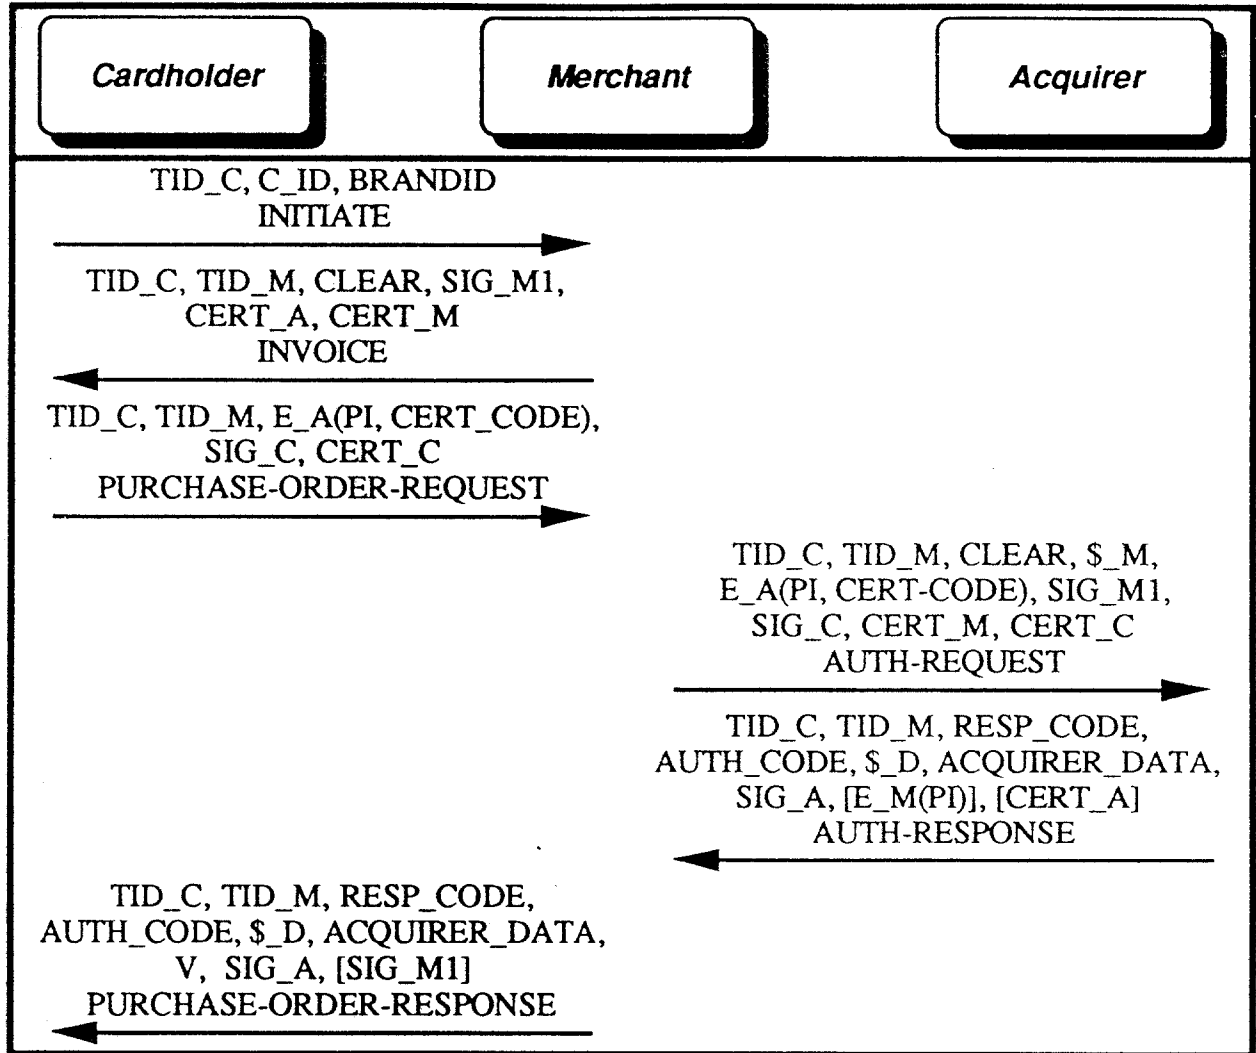

This is like the basic purchase order message flow, except that the INITIATE and INVOICE messages are omitted, and the PURCHASE-ORDER-REQUEST is accompanied by the Goods and Services Order, obtained from catalogs, CD-ROM, etc.

Composite Fields/Symbols

<i>Parameter</i>	<i>Definition</i>
COMMON	“information held in common by all parties” TID_C, TID_M, MFLAGS, \$\$, ID_M, DATE, NONCE_M, C_ID, H(GSO), H(V)
CLEAR	“information transmitted in the clear” MFLAGS, ID_M, DATE, NONCE_M, H(COMMON), H(GSO), H(V)
PI	“payment instructions” \$\$, H(COMMON), PAN, R_C, CARD_EXPIRATION, EXPIRE_DATE
SIG_M1	“merchant’s signature in INVOICE and AUTH-REQUEST” S_M(H(COMMON), H(CERT_A))
SIG_C	“cardholder’s signature” S_C(H(E_A(PI)), H(COMMON))
SIG_A	“acquirer’s signature” S_A(RESP_CODE, AUTH_CODE, S_D, ACQUIRER-DATA, H(COMMON))

**Purchase
Order with
Inline
Authorization
Flow**

SEPP over WWW

- Server sends an OFFER message marked
CONTENT-TYPE: APPLICATION/x-SEPP.
- OFFER message may be dealt by external
viewer (to allow 'snap-on' implementations).
- The OFFER message contains slightly-
modified-HTML form.
- This HTML form does not have embedded
info.
- New HTML tag: <PAYORDER>
- New attribute PAYINFO=VALUE

IBM Research

HTML Forms Additions

<i>Value</i>	<i>Description</i>	<i>Provided by</i>
CCNAME	Credit card type	Cardholder
CCNUMBER	Credit card number	Cardholder
EXPMONTH	Month of expiration	Cardholder
EXPYEAR	Year of expiration	Cardholder
CERTCODE	Certificate Salt Value	Cardholder
R_C	Cardholder Random Number	Cardholder
TID_C	Cardholder Transaction Id	Cardholder
SHIPTO	Ship to Address	Cardholder
AMOUNT	Total amount	Merchant
CURRENCY	Currency of Amount	Merchant
CARDTYPES	List of Credit Card Brands Acceptable for Payment	Merchant
PIVALIDITY	Expiration Date of Payment	Merchant
URLPAY	URL for Payment Protocol	Merchant
URLSUCCESS	URL for Browser on Success	Merchant
URLFAILURE	URL for Browser on Failure	Merchant

SEPP over E-Mail

- Use when merchant and cardholder cannot interact (e.g. buying from CD-ROM when disconnected)
- SEPP messages are sent as a MIME types, marked by:
CONTENT-TYPE: APPLICATION/x-SEPP.
- INITIATE and INVOICE messages omitted

IBM Research

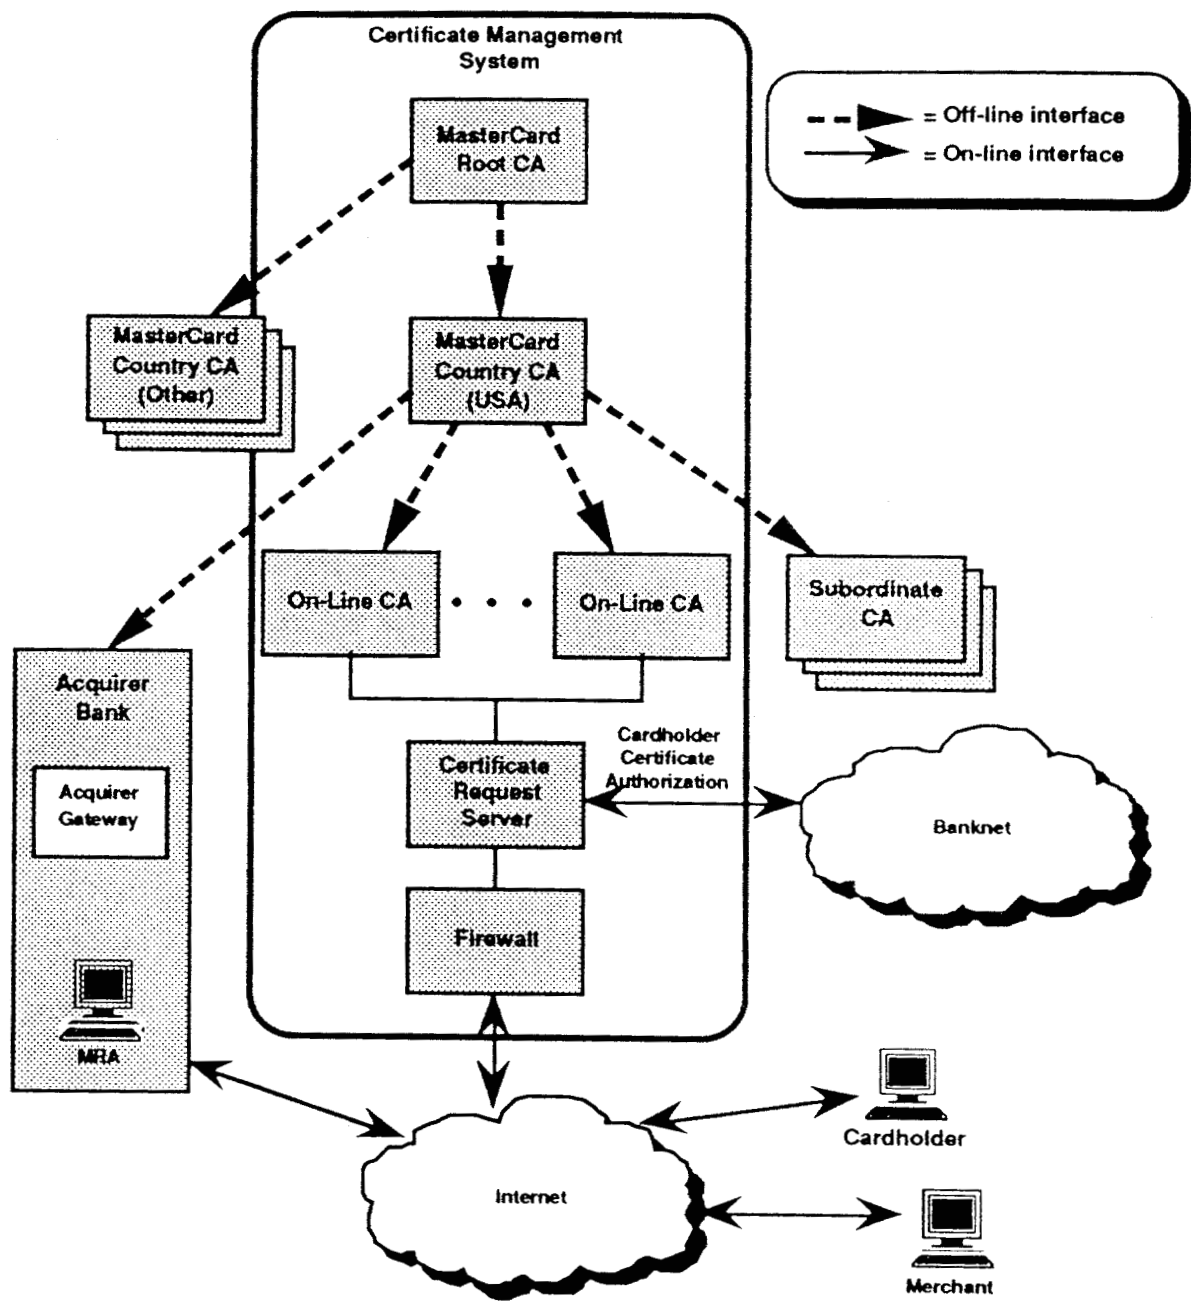

Figure 1. MasterCard Certificate Management System Architecture

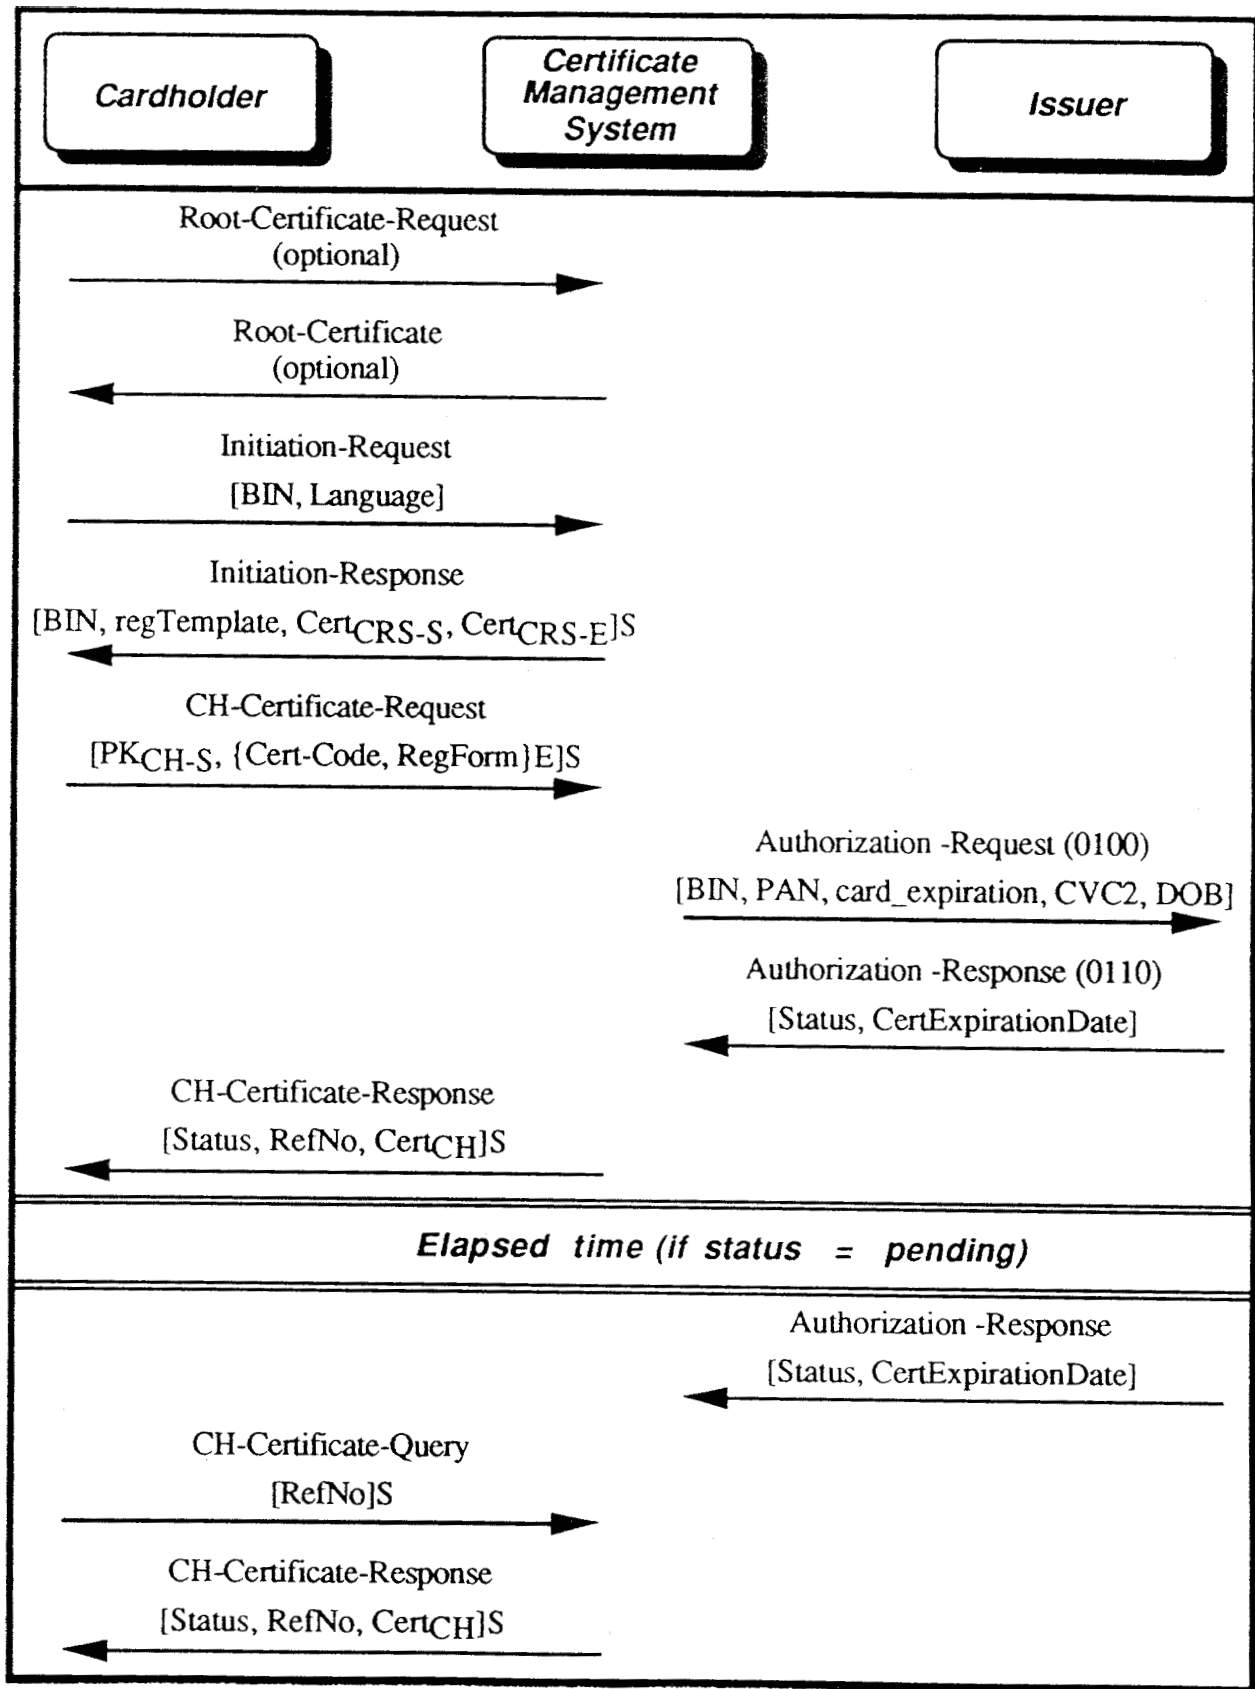

Figure 2. Detailed Cardholder Certificate Issuance Process

X.509 Certificate Field Name	Origin of data
Certificate.version	CA
Certificate.serialNumber	CA
Certificate.signature.algorithmIdentifier	CA
Certificate.issuer	CA
Certificate.validity	Issuer via Banknet Transaction Authorization response, or default value assigned by CA
Certificate.subject	CA
Certificate.subjectPubicKeyInfo	Cardholder
Certificate.issuerUniqueID	Reserved for future use.
Certificate.subjectUniqueID	Reserved for future use.
Extension.authorityKeyIdentifier	CA
Extension.KeyAttributes	Reserved for future use.
Extensions.certificatePolicies	CA
Extensions.keyUsageRestrictions	CA
Extensions.subjectAltName	Optional - cardholders e-mail address.
Extensions.subjectDirectoryAttributes	Reserved for future use.
Extensions.basicConstraints	CA
PrivateExtensions.brandID	Issuer via Banknet Transaction Authorization response, or default value assigned by CA
PrivateExtensions.accountValidationCode	CRS computes this value
PrivateExtensions.merchantAcquirerIDCode	Not applicable for cardholder certificates.
PrivateExtensions.certificateType	CRS sets to Cardholder
PrivateExtensions .merchantAuthorizationFlag	Not applicable for cardholder certificate requests (flag is not set).

Conclusions

- Convergence: now STT and SEPP; they will converge, too.
- SEPP advantages: open, free, scope (Web!), efficiency, security.
- IETF - open comments, convergence into standard

STRUCTURING STRATEGIC TRANSACTIONS

Wayne A. Martino, Esq.
Newton D. Brenner, Esq.
Brenner, Saltzman & Wallman
New Haven, Connecticut

I. DEFINITION

A Strategic Transaction is a collaborative relationship which helps each party leverage existing resources to achieve strategic business objectives and often involves the alignment of technological innovation, organizational resources, management expertise, entrepreneurial abilities and capital. Typically, these relationships are between large established corporations and smaller entrepreneurial or emerging growth companies with a technological advantage. Emerging companies generally find it difficult to obtain and commit the financial and human capital necessary to conduct the research and development activities necessary to develop products in order to maintain their technological advantage as well as to market them. Consequently, relationships with established companies with a strong market presence or distribution capacity may be advisable.

A company may enter into a strategic transaction with many different parties often with a parallel or complementary course of development. In addition, the technology or product generated from one relationship may have broader applications that may be used in other relationships.

II. CHOOSING A STRATEGIC PARTNER

Choosing a strategic partner is the most critical element of success. Both sides should objectively evaluate the following criteria in order to determine the likelihood of success:

1. **Compatibility of Goals.** Do the parties have compatible expectations and objectives? The business interest of either party may either reinforce the possibility of success or lead to future conflicts.
2. **Mutual Incentives.** Both parties must have an expectation of, and receive, significant benefit in order to have the proper incentive to maintain a collaborative relationship.
3. **Mutual Commitment.** How committed are the parties to overcome unexpected development obstacles? What is the track record of each party in solving problems?
4. **Responsiveness.** Do the key executives in each company have the proper authority so that a crisis can be confronted and resolved expeditiously? Is there flexibility to restructure to overcome unexpected development problems or changes in the market? Is there a personal contact with a key executive who sees the strategic logic of the relationship and is willing to risk some career capital?

5. **Longevity.** Are the parties' expectations of the duration of the relationship consistent with the potential development cycle?

III. ADVANTAGES AND DISADVANTAGES

A. Advantages to Large Established Company.

1. **Leverage Existing Resources.** Combine strong distribution, marketing and customer contacts with technological advantage.

2. **Expand or Maintain Market Presence.** Enhance existing products by filling in gaps in product lines or expanding into new products that may fit into strategic marketing plans or reduce risk of product obsolescence.

3. **Lower Cost of Development.** Lower labor costs and overhead are the hallmark of smaller companies.

4. **Access to Entrepreneurial and Technological Acumen.** In addition to the hope for cross pollination of such skills to its employees, a different perspective may be valuable because it is not constricted by the traditional methodology and view of the established company.

5. **Secure Necessary Technology or Research and Development or Keep Same from Competition.** Large companies are not always appropriate incubators for technological innovation. A strategic relationship may be necessary to preempt the technology or product from being available to a competitor.

6. **Speed of Technological Innovation.** Corporate culture of large companies may not allow it to remain current with technological innovation in emerging growth areas.

7. **Financial Upside.** Large company receives benefit of increased valuation which may be influenced by the success of the collaborative relationship.

8. **Low-Risk Acquisition Candidate.** Collaborative relationship will allow full evaluation of emerging company prior to decision of business acquisition. Initial investment at lower valuation will also reduce ultimate acquisition costs.

B. Advantages to Small Emerging Company.

1. **Validation.** Strategic relationship with established company can validate emerging company's technology or product and create tremendous credibility with customers, banks and other investors. Additional publicity and exposure may result in other strategic relationships and allow for better valuation in future financings.

2. **Ability to Focus on Core Capabilities.** Creating a fully integrated company is difficult especially in rapid growth, technologically dynamic industries. Focus and ability may be on product development without the burdens and distractions attendant to marketing, manufacturing and delivering products to market and service customers.

3. **Source of Additional Capital.** Initial cash infusion can reduce or eliminate financial strain and fund product development, marketing or creation of organizational infrastructure. Future revenue stream from royalties or manufacturing can finance future growth.

4. **Access to Experienced Managers to Fill Organizational Gaps.** An emerging company may have innovative product or intelligent marketing strategy but lack financial or human capital to conduct manufacturing, quality assurance, maintenance and field support. Regardless of whether the emerging company plans on becoming fully integrated or chooses to replicate the practices and procedures of the established company, exposure to experienced managers should speed development and accelerate learning curve.

5. **Speed to Market.** Technological and product innovations may only have a short lead time over competitors in which to bring products to marketplace.

6. **Access to Mature Distribution Channels to Broaden Market Exposure.** Some market opportunities can only be exploited by large companies with established track records and contacts.

7. **Lower Cost Financing Alternative.** Return on investment should not be the primary objective of the large company. Consequently, better valuations of equity and less dilution to owners of emerging company may be obtained in dealing with a financial investor.

C. Risk to Large Company.

1. **Market Risk.** Does the large company lose the opportunity to develop the expertise internally? If the venture is a failure, would the established company lack the expertise and technology to pursue the market opportunity independently or will it be too far behind the development curve?
2. **Financial Risk.** Unsuccessful development and worthless investment. Will ultimate investment be larger than expected because of unexpected development problems?

D. Risk To Emerging Company.

1. **Loss of Independence.** An established company may have different marketing, product development or financial agenda resulting in possible loss of business opportunity while satisfying expectations of established company. What happens if there is a change in direction, focus or executive personnel of large company?
2. **Loss of Entrepreneurial and Technology Advantage.** Conflict between entrepreneurial independence in emerging company and the organizational inertia generally found in established company is inevitable and generally leads to delay and compromise. Examine potential for loss of key employees who may have business opportunities in other development programs that are inconsistent with the objectives of the collaborative relationship.
3. **Customer Isolation.** If marketing and distribution rights are relinquished, will the emerging company lose the understanding of the customer's needs which might have been the genesis of its competitive advantage? At the end of the development program will the emerging company have the marketing expertise to compete?
4. **Risk of Piracy of Proprietary or Confidential Information or Employees.** Although contractual arrangements will prohibit this behavior, financial resources and staying power of large company can overwhelm emerging company in the event of a violation.
5. **Unfavorable Future Valuation.** An emerging company may fail to diversify and build volume in other product areas because of dependence upon large company and need to accomplish objectives of large company. Analyze possibility of a chilling effect on other sources of capital or strategic relationships.

IV. STRUCTURE

The structure of the relationship should be driven by the objectives of the parties. The variables in determining structure include

- the strength and weakness of the parties
- the desired relationship of the parties
- the type of technology or product involved and its stage of development
- the target market and method of distribution
- the ultimate situs of ownership of the technology
- the expected reward of the parties for a successful development

A. **Business Relationship.** Generally, the on-going business relationship of a strategic transaction will fall into one of the categories enumerated below. In many circumstances, transactions may be a hybrid.

1. **Joint Venture.** Generally, this is an association where the parties combine their property and expertise to carry out a business enterprise in which there is a joint property interest and control and a sharing of profit and loss. A joint venture can be conducted in a limited or general partnership, corporation or limited liability company.

2. **Product Development Agreement.** In this relationship one party funds the development of the product in exchange for ownership, licensing rights, right to purchase the product on favorable terms or right to receive royalties on sales to third parties. The developer may obtain manufacturing rights or rights to exploit the technology or products in specified market opportunities. Funding is usually based on the satisfaction of milestones.

3. **Technology Exchanges.** Exchange of complementary technologies for mutual or individual development.

4. **Licensing.** The grant of authority to use or exploit core technology or sell products. This relationship may involve co-exploitation rights of the core technology or product and/or any enhanced or improved technology and may be segmented by market opportunities.

B. **Equity Participation Structures.** If funding is necessary to allow the emerging company to accomplish the strategic goals of the transaction or if the strategic transaction is a substitute for venture capital financing, the structure may include equity participation in the emerging company or in a defined market opportunity in addition to an ongoing collaborative relationship. The type of structure, the terms and conditions and complexity will differ greatly when dealing with an equity oriented strategic partner especially in the areas of valuation, control features, liquidity requirements and ownership objectives. For example, valuation may not be aggressive because the primary focus is on achieving a return through the business relationship not a return on only a financial investment. The strategic partner may, however, request contractual covenants respecting mergers and acquisitions and other strategic relationships with its competitors

and may insist on operating restrictions or control if milestones are not met or if performance is not to the plan. The strategic partner's view toward preemptive rights, participation in future financings, registration rights and other liquidity options may be different if it has used the transaction as a preemptive to an acquisition of the entire entity and wants to control the equity destiny of the smaller partner.

Equity structures can include participation through any, or a combination of, the following securities which may be done at the emerging company level or other legal entity in which the technology product is contributed.

1. **Common Stock.** Participation in equity in which upside and downside in proportion to percentage ownership.
2. **Preferred Stock.** Preferential return of capital and payment of dividends prior to distribution to owners. Possible conversion into common stock or equivalent or participation with common in equity growth.
3. **Convertible Security.** Debt or equity instrument which is convertible into equity at option of holder or may carry required conversion or redemption upon occurrence of certain events.
4. **Warrants or Options.** Right to purchase equity at specified price for specified period may be combined with loan or as additional incentive to enter into strategic transaction.

The terms and conditions of equity structures can be implemented through contractual arrangements but often material terms are incorporated in the certificate of incorporation or other organizational documents of the entity in which the equity participation is obtained.

C. **Alternatives to Equity Participation.** Often the owners of the emerging company do not want to have their ownership diluted, but are in need of additional funding. Alternatives to equity participation may be monetary or non-monetary support such as:

- advance payment, prepaid royalties or initial license fee
- research and development funding
- loans
- guarantee of third-party financings
- leasing of equipment or facilities
- provision of personnel
- market research study
- beta site testing for new products

V. MAJOR ISSUES

The following provides a checklist of major issues and terms and conditions of strategic transactions. Although representative of major issues, it is intended to be neither exclusive nor exhaustive.

1. **Rights to Technology.** Carefully delineate ownership and licensing rights regarding both core technology as well as enhanced and improved products with an affirmation of the owner's right to use preexisting information and activities outside the venture. To what extent do enhanced technologies or practices incorporate existing technology and create issues regarding ownership? Are there any limitations on the ability to work with competitors of the parties and will there be any post development collaboration?

2. **Decision Making and Control.** Which party will be in day-to-day control? Will there be joint decision making on major business decisions such as mergers and acquisitions, deals with competitors or other equity investments? What is the nature of the operating covenants and representation on the board of directors. Classes of stock may be used to ensure level of control both at shareholder and representation on board of directors.

3. **Proprietary and Confidential Information.** Incorporate covenants not to use or disclose confidential information and consider covenants concerning restricting competition or solicitation of employees both during, and after the termination of the relationship. All officers and key personnel of the emerging company will be required to execute non-disclosure and assignment of invention agreements.

4. **Changes in Direction.** Consider mechanisms to deal with stalemates and changes in strategies or policies. Although a critical issue, it is difficult to create an

acceptable external control mechanism. If decision making is at board of director level, consider use of outside directors or having structure which does not require unanimous decision making by board of directors. Fiduciary duties are different at the board of directors and shareholder levels.

5. **Use of Development Milestones.** Focuses the parties on specific goals and tasks to be accomplished and should introduce realistic expectations regarding feasibility and timing. Milestones may serve as the benchmark for providing additional funding or a trigger for transfer of ownership, manufacturing or distribution rights. The failure to accomplish milestones may allow termination of the relationship before a complete loss.

6. **Market Exploitation.** A balance must be obtained between the large company's desire to capture the broadest possible range of marketing rights and limited competition and the smaller company's desire to carve out areas of permitted activity in order to maximize market penetration and lessen the dependence on the large company. Major issue is the exclusivity which can be defined by geographical territory, field of use, product or application linkage or restrictions and duration. Exclusivity may be terminated upon the occurrence of any of the following events: failure to achieve sales or product levels, failure to make scheduled product introductions, failure to take specified levels of marketing activities, marketing of directly or indirectly competitive products.

7. **Manufacturing Rights.** Successful relationships can be built by maintaining the right to manufacture some or all of the product or supply key components. Manufacturing is critical because it retains the ability to protect and build technology.

8. **Equity Investment.**

A. **Type of Participation.** Identify nature, rights, privileges and restrictions of equity interest whether common or preferred, convertible security, warrant or option. Equity terms may include a preference in liquidation on investment with or without cumulative dividends. What are the nature of restrictions on distributions to the owners? Does the established company have a cash-out election at sale which may have a detrimental effect on the use of a pooling transaction in a stock transaction with a third party?

B. **Liquidity.** How will the larger company recoup its investment? Will it have demand or piggy-back registration rights if the emerging company goes public? Will it have rights of first refusal to purchase shares sold by the company or its principals or will it have a right to participate in the sale of equity to another? Will these rights have a chilling effect on other potential investors?

C. **Anti-Dilution Protection, Participation and Preemptive Rights.** Participation or preemptive rights may allow large company to maintain the same percentage ownership by participating in any new financing. Does the large company have the right to participate in any future financing? At what price, for how long and what exemptions or exclusions apply? Any repricing mechanism or distribution of additional shares if future financing done at price below that paid by established company?

D. **Puts, Calls and Redemption Rights.** Under what circumstances does either party have a right to require the purchase or require the sale of the other's

shares. Consider issue not only upon successful development but also if relationship fails or key manager or technological personnel depart.

E. **Tax and Financial Reporting Issues.**

1. **Recognition of Taxable Income Upon Initiation.** If technology is to be contributed to a new entity, the contributor may desire to avoid tax on the spread between its tax basis for the technology (e.g. cost to date) and the value of the technology derived from the party's relative contributions and percentage ownership. Non-recognition devices are available such as formation of new corporation with joint capital contribution or partnership or limited liability company organization. Sufficient rights to technology must be transferred to qualify for non-recognition treatment.

2. **Choice of Entities.**

- (i) Pass Through - Partnerships including joint ventures, limited partnerships and limited liability companies taxed as partnerships. Subchapter S corporation status is not available if corporate shareholder.
 - (a) One level of tax on profits
 - (b) Loss pass through to equity owners
 - (c) Flexible structuring alternatives in sale of business
 - (d) Advantageous tax free reorganization transaction is not available on sale of entity for stock.

(ii) Separate Taxpayers - C Corporations.

- (a) Profits taxed at corporate level and dividends fully taxed unless to corporate parent.
- (b) No utilization of loss unless 80% control by corporate parent
- (c) Sale of business for stock can fit tax free reorganization models - very advantageous.
- (d) Sale of assets for cash will involve double tax unless buyer willing to acquire stock of entity from existing owners

3. **Employee Issues.**

- (a) Opportunities to acquire stock at inception complicated by Section 83 rules concerning restricted stock
- (b) Qualified incentive stock option plan providing favorable tax (capital gain) potential cannot fit partnership entity

F. **Accounting Issues.**

1. **Financial Statement Presentation.** Parties may wish to capture or avoid presentation of entity's revenue, expense or net income on its financial statements. If partnership structure, capital account fluctuations will be reflected on partner's financial statements. If corporate structure, the carryover to corporate shareholder is as follows:

ownership above 50% - - full carryover of revenue, expense, income and loss
ownership between 20% and 50% - - net profit or loss carryover only
ownership less than 20% - - no carryover of revenue, expense, profit or loss

2. **Pooling of Interest.** Reporting of acquisitions as a pooling of interest is attractive from purchaser's perspective because the spread between the fair market value and book value of the assets will not be recorded as good will and will not be a drag on future earnings. Pooling treatment is not available if the purchaser already owns 10% or more of the equity at the time of purchase of the remainder or if the consideration is not for common stock.

3. **Audited Statements.** Besides giving comfort level to purchasers and/or parties to strategic transactions, if ultimate goal is to go public or be acquired by a public company, audited statements may be a necessity. If company has no material amount of inventory, prior years financial statements may be able to be reconstructed in order to provide an audit opinion to cover those years.

On-line Services and Internet Strategic Alliances

Internet World

Peter Marx

The Marx Group

October 31, 1995

A Hypothetical Case Study

- Tennis Universe Magazine: strategy and positioning
- Potential partners
- Selected strategic alliances
- Picking partners
- Structuring relationships

Tennis Universe Magazine

- Assets to leverage
 - 2 million readers
 - Recognized name
 - Editorial and product databases
 - Search software for historical and current feeds
- Strategy
 - To become the place for tennis related information, advertising, announcements, discussions and transactions

Potential Partners

- America Online
- The Microsoft Network
- ATT Interchange
- NYNEX, or
- Own Web Site

America Online

- Internet-related acquisitions
 - Ubique Ltd. -- software for Internet chat
 - Global Network Navigator
 - Web Crawler -- search & retrieval
 - WAIS - publishing tools
 - Medior - interactive media applications
 - Booklink Technologies -- software & browser
 - Navisoft Technologies -- publishing tools
 - Advanced Network & Services -- high speed network infrastructure services
 - Redgate Communications -- multimedia & interactive marketing services

America Online (continued)

- Strategy: Online community linked to the Internet
- Online Games Partnerships
 - Yoydyne Entertainment
 - NTN Communications
 - Simutronics
 - Strategic Simulation
 - Interactive Broadcasting
 - Boxer Jam Productions

America Online (continued)

- Distribution Agreements (20 plus airplane)
 - Compaq
 - Packard Bell
 - Gateway 2000
 - DEC
- Content Alliances -- pushing for exclusives
 - Reuters
 - Time
 - Sports Channel
 - Pro Football Insider
 - ABC Sports
 - Greenhouse -- iGolf

America Online (continued)

- Revenue sharing -- varied
 - 80/20 on excess usage
 - Bounty -- \$15 per new customer
 - 85/15 on ad revenue
 - 90/10 on transactions fulfilled off-line

The Microsoft Network

- Strategy: Seamless Internet integration & vehicle for electronic commerce
- CD-ROM
- Windows 95
 - 50 million potential customers
 - anti-trust issues
- Revenue sharing
 - 70/30 on-line charges
 - 80/20 ad revenues
 - 95/5 transactions fulfilled off-line
- Web Links \$2500 - \$15,000 per month

The Microsoft Network (continued)

- Alliances

- Individual Inc. (10% equity interest)
- TCI (20% investor in MSN)
- Spyglass
- UUNET
- NBC (moved from AOL and Prodigy)
- 800 Flowers
- Reuters
- Many content partners

ATT Interchange

- ATT customer base
- Numerous other ATT efforts:
 - Business Network
 - Internet access (Netscape and BBN Planet)
 - ImagiNation Network (Sierra On-Line, NTN Communications, Dynamix)
 - ATT network
 - Local service
- Strategy: Brand publishers' platform

ATT Interchange (continued)

- Content Alliances
 - The Washington Post
 - Gartner Group
 - Ziff-Davis
 - Journal Register
 - Minneapolis Star Tribune
 - Reuters
- No plan to own content

ATT Interchange (continued)

- Revenue Split
 - Content fees: 70% publisher -- 30% ATT
 - Monthly Interchange fee: 100% ATT
 - Overtime connect charges: 5% publisher -- 95% ATT
 - Ad revenue: 85% publisher -- 15% ATT
- Publisher retains brand identity
- Internet access in Summer '96

NYNEX

- Dominant voice telephone provider within territory
- Internet access potential
- Potential of ISDN
- Strategy: unclear
- Must do acquisitions to play any meaningful role

NYNEX (continued)

- Alliances

- Infolook
- Dow Jones (wireless)
- Newsday (home shopping)
- Prodigy
- Bell Atlantic (wireless)
- Numerous divestitures of computer company acquisitions
- Viacom (\$1.2 billion)
- Bell Atlantic, PacTel and Creative Artists (\$300 million)

NYNEX (continued)

- NYNEX Information Resources Company (yellow pages)
 - Consumer information database
 - Electronic commerce
 - Complementary to Tennis Universe's database

Own Web Site Considerations

- Opportunities:

- Large and rapidly growing Internet audience
- Control versus burden to manage infrastructure
- Revenue opportunities -- subscription, advertising and transactions

- Challenges

- Security
- Development cost and risk
- Marketing
- Will Internet consumers pay?

Factors Impacting Future Marketing Positions

- Broadband networks
- Telecom deregulation
- Convergence
- Internet tools available
- Evolving Internet business model

Key Factors in Selecting Partners

- Market reach including Internet access
- Revenue split
- Time and financial investment required
- Technological strength
- Infrastructure
 - Tracking usage, ads and royalties
 - Transaction capability
 - Payments mechanisms

Structuring Relationships

- Operational
 - Cultural fit
 - Marketing
 - Development
 - Security
- Financial
 - Royalty splits -- Are we really moving from 20-80 to 70-30?
 - Expenses

Structuring Relationships (continued)

- Legal
 - Owning the customer
 - Protecting intellectual property
 - Exclusivity
 - Responsibility for liability, privacy, porn, etc..?
 - Term

Conclusions

- Set up own Web site
- Pick one partner
- Deal points
 - Non-exclusive
 - Set own prices
 - Keep a “fair” share of revenues
 - Maintain primary customer contact
 - Protect brand identity

Presentation

Designing & Maintaining Your Web Site

A Presentation for
Fall Internet World 1995
developed and presented by
Peter Morville
Argus Associates

November 2, 1995

Peter Morville

-
- Vice President, Argus Associates
 - information design consulting (Web sites)
 - Argus / UM Clearinghouse
 - Mgr of Online Services, Michigan Comnet
 - online community development
 - Background in Information and Library Studies (University of Michigan)
 - not a “techie”

Who Are You?

- Roles
 - MIS, Internet consultants, marketing, senior management?
- Experience
 - Surfing the Web?
 - Developed at least one Web site?
 - Will develop first Web site soon?

What We'll Cover

- Introduction to Web site development
- Interdisciplinary team approach
 - **architecture**, design, marketing, technical, project management
- Phases of Web site design
 - research, **conceptual design**, planning for production, production, maintenance
- Evaluation
- Keeping Current
- *Note: seeing through eyes of architecture team*

Introduction to Web Site Development

- What types of organizations develop Web sites?
 - businesses, universities, nonprofits, government agencies, publishers, etc.
 - from small to large, rich to poor
- Why?
 - marketing, sales, information dissemination, customer service, strategic positioning, return on investment

Introduction to Web Site Development (cont.)

- Under what circumstances?
 - well funded strategic project with extended timeline
 - no time, no budget
- Who develops Web sites?
 - internal staff and/or external consultants
 - ideally an interdisciplinary team approach
 - marketing, architecture, design, technical

Introduction to Web Site Development (cont.)

- Methodology for Web site development
 - interdisciplinary teams
 - phases
 - more an art than a science

The Marketing Team

- Focus on the customer / audience
 - who are they, how do we attract them to the site, how do we get them to return?
 - synthesis of conventional market research with Internet demographics
- Integration of traditional and online marketing
 - cross referencing between print and online promotions
 - exploration of online marketing and advertising channels

The Architecture Team

- Create information architecture that supports
 - ease of navigation for casual browsing and/or directed searching
 - site extensibility
- Architectural blueprint
 - organization of information, labeling conventions, application of search capabilities, use of navigational aids
 - varying levels of detail (site level, page level)

The Design Team

- Develop design philosophy
 - balancing form and function (graphics)
 - design for multiple platforms and browsers
- Design graphic and textual elements
 - graphic design
 - page layout
 - copy editing
 - HTML page production

The Technical Team

- Consultant to other teams
 - what's possible, application implications
- Production / maintenance
 - tools, processes, procedures for initial development and ongoing operation of site
- Develop / integrate advanced software tools
 - searching, online databases, registration / authentication, conferencing

The Project Management Team

- Team coordination and communication
- Keep project within budget and on time
- Manage financial and legal issues
- Report to senior management
- Communicate team needs to senior management

Working Together

- Project manager coordinates
 - identify areas of overlap
 - more importantly, fill gaps
- Considerable collaboration
 - particularly in research and conceptual design phases

Phase I: Research

- An information gathering phase to identify:
 - vision
 - mission and goals
 - audience (s)
 - content definition and collection
 - contacts and communications

Why Vision is Important

- Paradigm shift in communication and information sharing
 - Long term implications on par with printing press, telephone
 - Internet is new and dynamic environment
 - processing speed and bandwidth increasing
 - interface improving
 - people and businesses learning to use the technology

Why Vision is Important (cont.)

- What will this mean to your business? Your industry?
 - do you need to change to survive?
- Leveraging the medium (3 levels)
 - 1. marketing
 - 2. sales / online transactions
 - competes with existing sales programs
 - 3. innovation
 - new products and services
 - new markets

Mission and Goals

- Matching missions
 - rethinking your mission statement
 - your organization and your Web site
- Identifying and examining goals
 - long term strategy vs. short term return on investment
 - experimentation vs. mission critical
 - sales, marketing, information dissemination, customer service

Audience(s) Definition

- Identify your target audience(s)
 - consumers, businesses, business partners, investors, internal staff, journalists
- Audience analysis
 - does / will your audience use the Web?
 - what information is most important to them?
 - how do they currently seek / find information

Content Definition and Collection

- Content brainstorming
 - facilitated sessions with individual divisions / departments
- Content analysis
 - towards a collection development policy
 - what's in / what's out
 - setting priorities: from dreams to reality
 - costs (production, maintenance), copyright issues
 - present vs. future

Contacts and Communications

- Who are the experts within the organization with respect to:
 - various areas of content
 - audience
 - marketing
 - graphic design
 - technical infrastructure
- How will teams communicate with:
 - each other, senior management, staff, customers

Phase II: Conceptual Design

- Defining **what** the Web site will be
 - form and function
- Architectural blueprint
- Design philosophy
- Templates for main and subsidiary pages
 - integrating text and graphics
- Design of advanced tools / features
- Inclusionary approach (“buy-in”)

What is Web Site Architecture?

- Organization of information
- Labeling of information
- Cross-referencing
- Application of search capabilities
- Elements of navigation

Why is Web Site Architecture Important?

- User's perspective
 - navigation and usability
 - support casual browsing and directed searching
 - avoid confusion and frustration
- Organization's perspective
 - support goals of marketing team
 - allow for smooth growth of Web site without costly reengineering

Top Level Pages

- Gateway pages
 - initial point of entry to Web site
 - serve marketing goals (billboards for “splash”)
 - serve a shepharding role (e.g. redirection to audience specific pages)
- Main menu pages
 - the “home page” as an information system interface
 - focus on navigation and ease of use
- Separation vs. integration

Organization of Information

- Organization schemes:
 - subject or topic, audience, department, chronology, geography, product or service, format, static vs. dynamic
- Metaphor exploration
 - an online store, library, magazine, etc.
- Consider multiple schemes

Labeling

- Use the language of your audience
- Practice consistent usage and syntax
- Investigate use of controlled vocabularies or thesauri, but realize don't always scale well

Ideas for Organizing and Labeling

- Card sorting
 - index card for each content item
 - organize cards into groups and label those groups
 - try with staff, senior management, intended audience(s)
- Review organization schemes of other Web sites
- White board brainstorming

Hierarchical Organization

Hierarchical Organization Schemes

- Information divided into mutually exclusive subdivisions
- Classes and subclasses (parent / child)
- Very common and familiar way of organizing information
 - org. charts, animal kingdom, library catalogs
- Important to balance breadth and depth
 - broad vs. narrow
 - deep vs. shallow

Broad and Shallow

Narrow and Deep

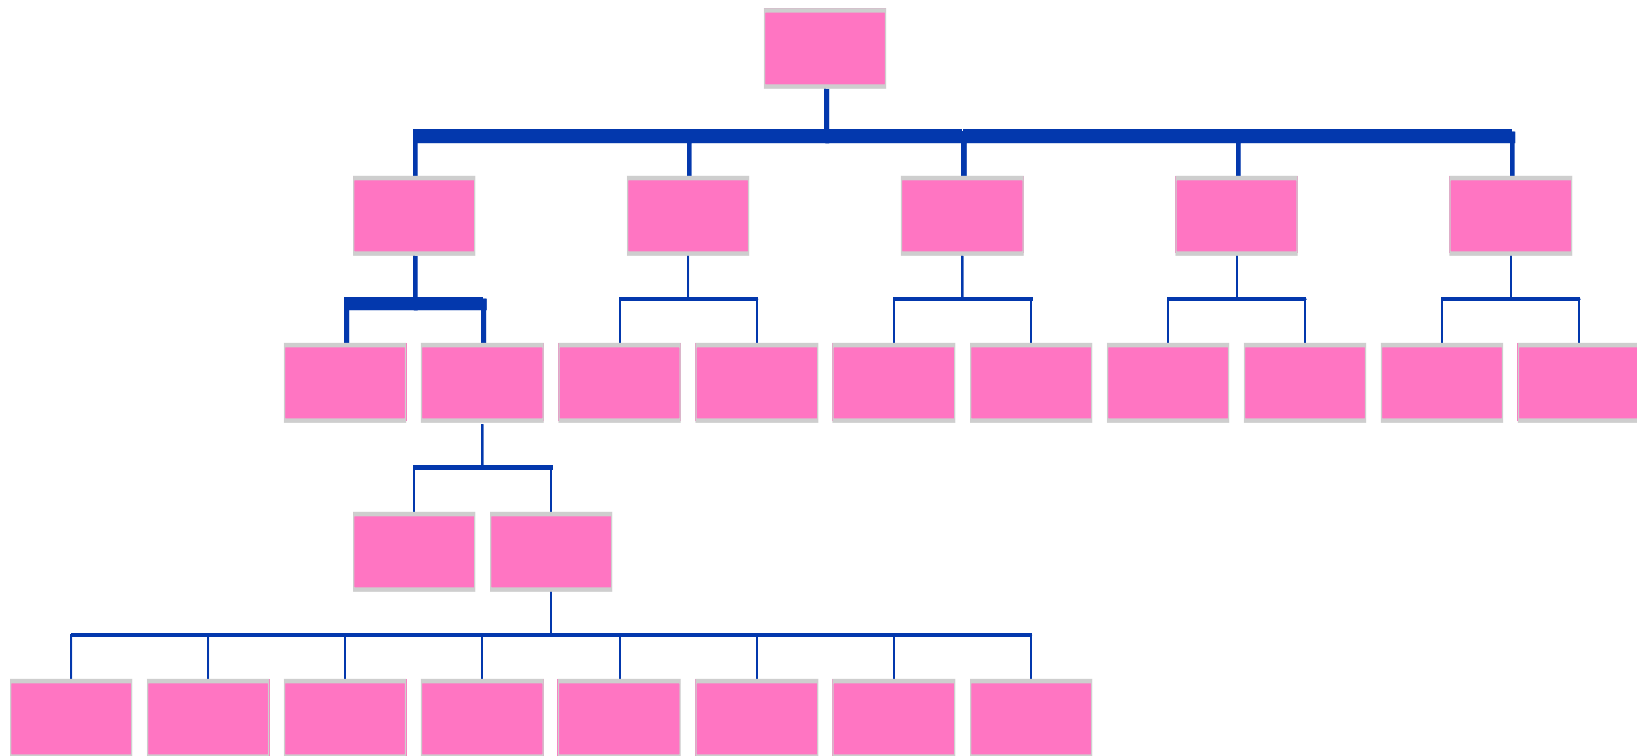

Heuristics for Hierarchies

- Limit number of choices per menu to 8-12
- Limit number of hierarchical levels to 3 or 4
- Studies in human-computer interaction indicate hourglass structure works best (8-3-3-8)

Hourglass Structure

- Highly flexible system of organization
- Links can connect
 - words, phrases, documents, images, video and audio clips
- Supports multiple pathways to the same information
- Can be very disorienting to user
- Added demand on navigational elements
- Can be used to compliment hierarchy

Hierarchy and Hypertext

Navigation

- Navigational elements implemented at page level but site-wide implications
- Goals
 - provide sense of context and consistency
 - facilitate browsing and searching
 - balance ability to get anywhere from anywhere with desire to avoid clutter

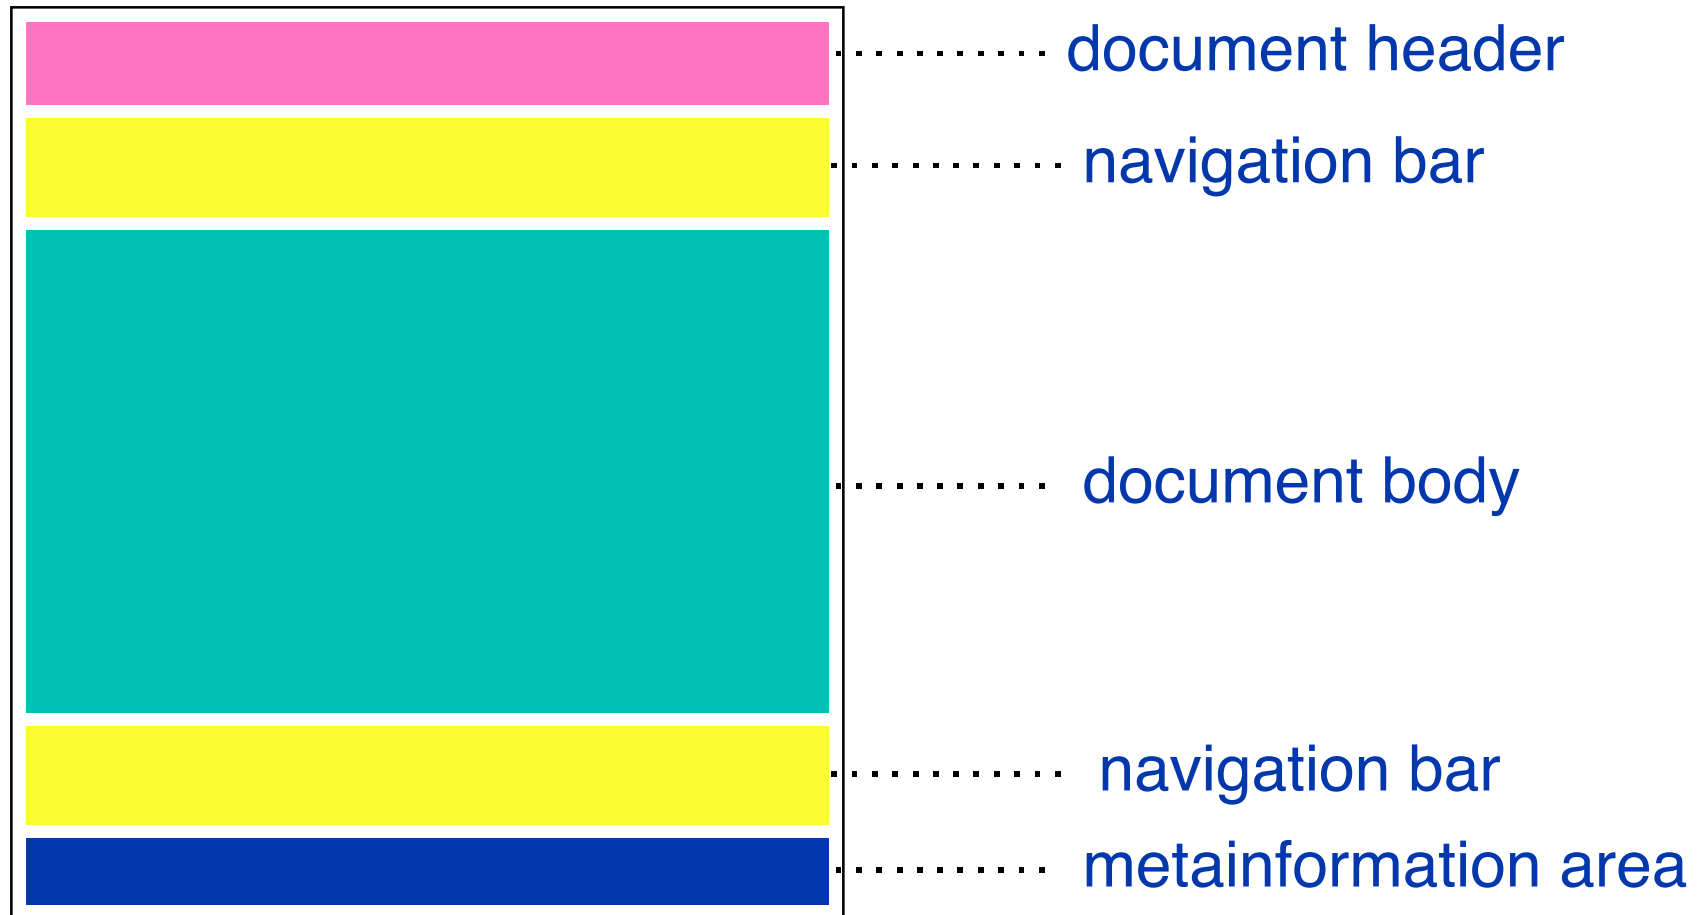

Navigation (cont.)

- Consistent use of landmarks
 - organization of elements on a page
 - links to gateway, index, and/or section pages
 - links to searching interface
 - other popular sections?
- Textual and/or graphical aids
 - hypertext links, arrows, maps, icons

Elements on a Page

Document Header

- Provide contextual clues through use of text and/or graphics
- Textual Clues
 - inclusion of Web site title
 - textual links showing position in hierarchy
- Graphical Clues
 - common elements from Gateway page
 - use of size
 - use of color schemes

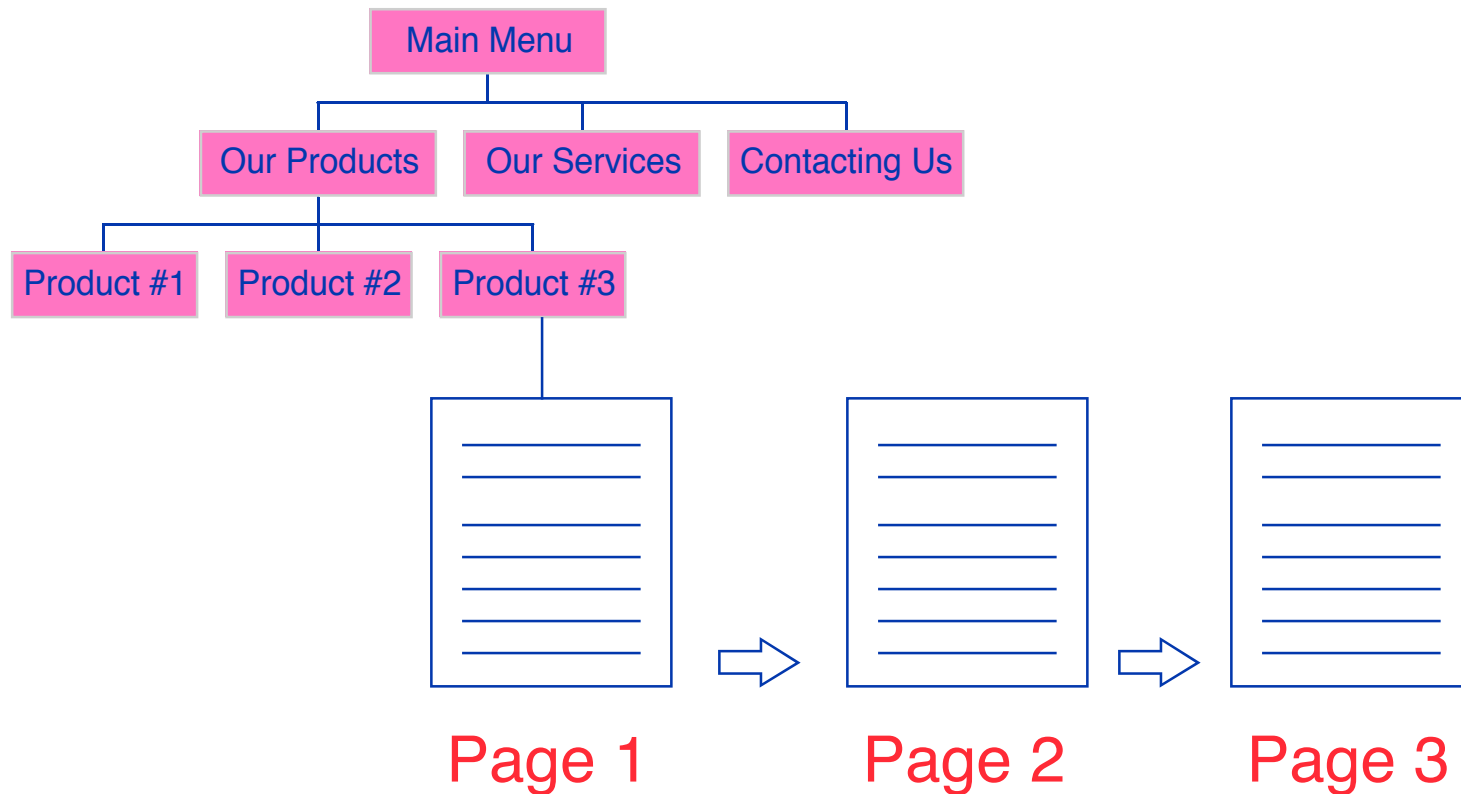

Navigation Bar

- Integration into header
- Include at top and bottom
- Specific links
 - main menu, our products, our services, contacting us
- General navigation bar
 - next page, previous page, move up a level

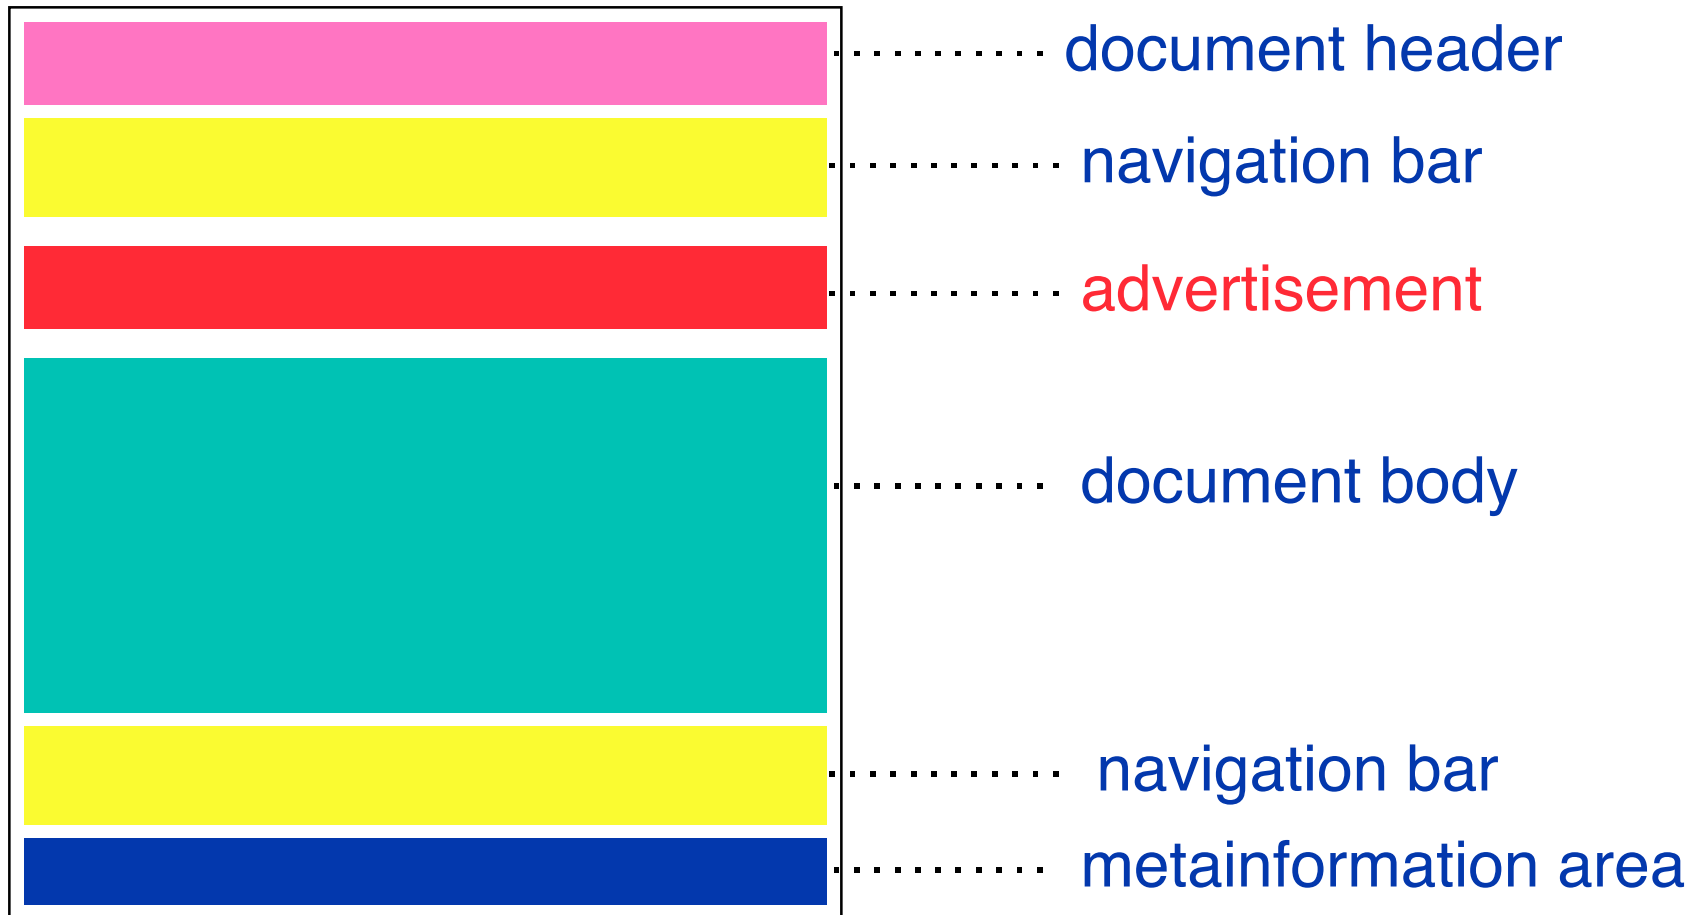

Navigation Bar (cont.)

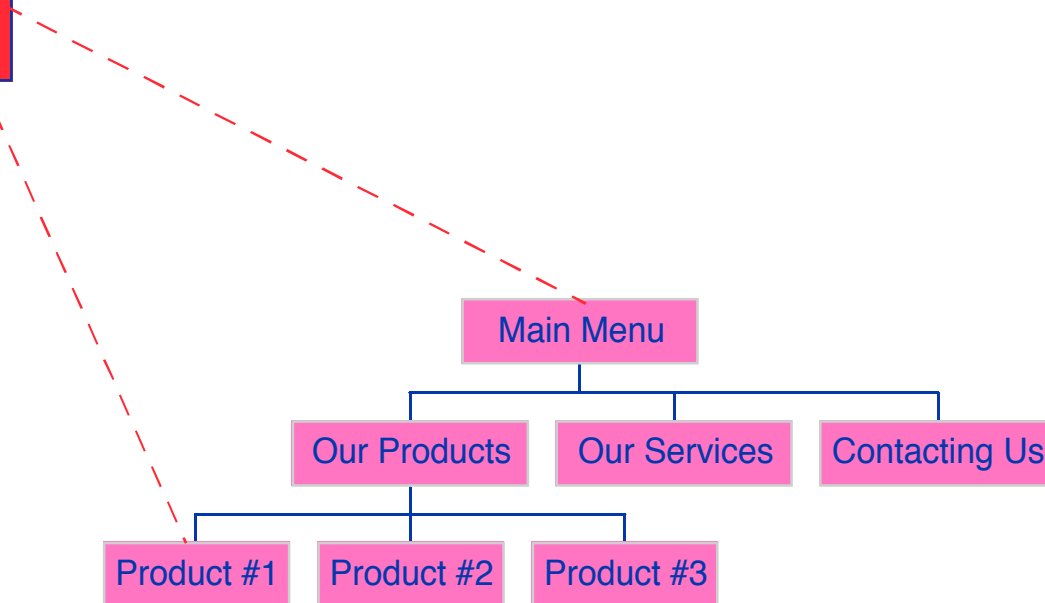

Architecture and Marketing

Architecture and Marketing (cont.)

Billboard

Architecture and Marketing (cont.)

- *Case study: Netscape Communications*
 - <http://home.mcom.com/>

Searching Your Web Site

- What will be searched?
 - menu and document titles
 - index with fields (keyword, author, etc.)
 - full text of all documents

Searching Your Web Site (cont.)

- Query interface design
 - clear explanation of what is being searched
 - clear explanation of how that body of information can be searched (Boolean, proximity, adjacency, string, case sensitive, nesting, relevance ranking)
 - explicit relationship between browsing and searching interfaces
 - novice and expert interfaces

Advanced Tool Design

- Registration and authentication
- Interactive online databases
- Conferencing software for group discussions
- Online forms for questions and/or feedback

Usability Testing

- Prototype
- Test on intended audience(s)
 - talk out loud
 - casual browsing
 - directed searching (example searches)
- Redesign
- *Case study: Sun Microsystems*
 - <http://www.sun.com:80/sun-on-net/uideesign/sunweb/>

Phase III: Planning for Production

- **How** the Web site will be implemented
- Needs analysis and resource identification
 - people and technology
- Technical and architecture teams
 - information ownership blueprint
 - who creates, manages, owns the information
 - process ownership blueprint
 - how does it get from the information owner onto the Web site (centralized vs. decentralized)

Phase III: Planning for Production (cont.)

- Data processing procedures
 - how much information already in digital formats
 - explore cost of conversion vs. data entry
 - in-house vs. outsourcing
- Project Management
 - planning of parallel processes
 - identification of dependencies
 - keep to budget and timeline

Phase IV: Production

- Ideal
 - filling in blanks or painting by number
- Reality
 - demand on project manager to keep on time and within budget (crisis management)
- Parallel Processes
 - staff training, creation of documentation
- Beta testing
 - by teams and intended audience(s)

Web Site Launch

- Avoid launching too early
 - one chance to make first impression
 - construction signs and shallow sites do not leave good impressions
- Integrated marketing effort
 - traditional marketing channels
 - press release, advertising, print literature, business cards, etc.
 - Web based marketing
 - directories
 - discussion groups
 - online advertising

Phase V: Maintenance

- Keeping content fresh / up to date
- Responding to user feedback
- Managing growth
- Evaluation of success

Web Site Evaluation

- Standard usage logs
- Registration and authentication
- User surveys
- Lead tracking

Presentation Review

- Interdisciplinary team approach
 - **architecture**, design, marketing, technical, project management
- Phases of Web site design
 - research, **conceptual design**, planning for production, production, maintenance
- Evaluation

Keeping Current

- Technology changes but design philosophy remains stable
- Keep up with evolving capabilities
 - HTML, Java, VRML
- Review resources for Web design
- Hire a consultant

Presentation Roadmap

Introduction

Commerce

Communication

Collaboration

Wrap-Up

The Starting Point: Commerce on the Web

- What does it mean?
 - *Selling goods and services...*
 - *or is it much more?*
- Sales support, marketing, business development
- Background Info
 - *reputation and history*
 - *market position*
 - *people*

Commerce Is

- The exchange of money for goods and services
- The flow of Information
 - *To key audiences*
 - *Already a mainstay on the Internet*

Does it make sense to start with commerce?

- Point-of-Sale is intriguing
 - *in a nickel and dime sort of way*
- Its simplicity makes it an ideal lens

Key Words for the Day

- **Commerce**
- **Information**
- **Infrastructure**
- **Knowledge**
- **Collaboration**
 - ***Teamwork***
 - ***Common Cause***

Internet Teamwork???

- **With others in your organization**
- **With external partners and allies**

Presentation Roadmap

Introduction

Commerce

Communication

Collaboration

Wrap-Up

**The
Organization**

**Real-World
Operations**

- Fulfillment
- Billing
- Inventory
Management

**Traditional
Channels**

Organizational Information Resources

**Point
of Sale**

**Network
Infrastructure**

The Internet

- Customers

**Real-World
Operations**

- Accounting
- Payroll

**Traditional
Channels**

**The
Marketplace**

Commerce Model I

So Who's Buying and Selling on the Net Today?

So what's the hold-up?

- Ubiquitous Access?
- Secure Transactions?
- How about customer behavior?

**The
Organization**

Organizational Information Resources

**Real-World
Operations**

**Real-World
Operations**

Pre-Sale Support

- Catalogs
- Demos
- Inquiry Response

**Point
of Sale**

**Network
Infrastructure**

Post-Sale Support

- Instructions
- Help Desk
- Follow-Up

**Traditional
Channels**

The Internet

**Traditional
Channels**

- Customers
- Potential Customers

**The
Marketplace**

Commerce Model II

You Need Information to Clinch the Sale...

- like product and service descriptions
- product descriptions + pictures + ordering information = **CATALOGS**

Visiting LL Bean

Identity Counts, Because

- **Prospects Want Context**
 - ***Who we are***
 - ***What we do***
 - ***Our markets and spheres of operation***
 - ***Our specialties***
 - ***Our mission and values***
 - ***Our history***
 - ***Our view of the future...***

These all play a part in disposing a prospect to buy

Web Commerce is more about Web Communication

...than point-of-sale
transactions...

and success in
communication is as much
about *how* you
communicate as *what* you
communicate.

Building prospect confidence is key

- You can answer his or her unique needs
- You understand those needs perfectly
- He or she *belongs* in the community of interest you anchor.

Visiting Coca-Cola

**Sometimes Web Commerce
isn't about point-of-sale at all.**

Presentation Roadmap

Introduction

Commerce

Communication

Collaboration

Wrap-Up

Coke's Audiences

- young and hip to the Net
- looking for diversion, not hard-sell
- not wowed by the trappings of authority.
- other segments:
 - ***sports fans***
 - ***memorabilia collectors***
 - ***investors (lip-service, just in case)***

Coke's Web Messages...

- are life-style oriented. They say “Life is way-cool.”
- they don't say “buy some Coke right now.”

This is **MARCOM.**

It's an easy transition

- **from giving life-style *warm fuzzies* to ...**
- **providing useful information geared to life-style ...*or***
- **more serious areas of interest.**

Other Segments Join the Web's Global Audience

- **media**
- **securities analysts**
- **other professionals**
- **institutional investors**
- **researchers**
- **the intellectually curious**

**The
Organization**

Organizational Information Resources

**Real-World
Operations**

Organizational Knowledge

**Real-World
Operations**

Pre-Sale Support

**Network
Infrastructure**

Post-Sale Support

**Traditional
Channels**

The Internet

**Traditional
Channels**

- Customers
- Potential Customers
- Industry Allies
- Opinion Leaders
- General Audiences

**The
Marketplace**

Communication Model

The Trend...

- **Commercial content is becoming more serious**
- **This is especially evident in the services sector.**

Visiting IBM

Big Blue's Web Content

- **Identity elements**
- **“Image” elements**
- **Information elements**
- **Service elements**
- **“Fun” elements**

Big Blue's Web Intent

- **Communicate the full scope of its operations**
- **Sell you on its value.**

IBM's Stylistic Hallmarks

- use of mixed-media modes
- solid intellectual content
- no hesitation to use heavily *textual* elements

RESULT: a pretty comprehensive overview of the company.

Beyond Pure MARCOM

**a new wrinkle: presenting
corporate know-how, AKA...**

INTELLECTUAL CAPITAL

Intellectual Capital = Corporate Knowledge and Experience

**Organizational knowledge and
experience, as embodied in..**

- **market offerings**
- **systems**
- **research activities**
- **human resources**
- **business processes**
- **history and values**

AND...

Relationships

- with markets and customers
- with capital markets and investors
- with governments and regulators
- with industry allies
- with social entities
- within the enterprise
(at *all levels*)

Institutional Knowledge and Experience

**...becomes valuable only when it's
captured and shared.**

**The Internet offers the best means
for bringing this material to the
attention of stakeholders.**

Intellectual Capital in a Mixed-Media Key

As bandwidth expands and compression technologies improve, watch for an explosion of new approaches.

WEB PUBLISHING MODES

	Words	Images	Audio	Video	Page Layout
CERN	HTML				
Early Mosaic		-inline -"paged"	file-based .au <i>et al</i>	file-based .mpeg/.mov	"raw" (+ EPS Downloads)
					
2nd Gen. Browsers	forms	image maps			tabular
	DB searches	pull-push			"paged" (.pdf)
Helper Apps			streamed (RealAudio)	streamed (Xing)	

NEXT ... HOT JAVA ... VRML

But Don't Diss Text Yet

**It's poised for a
resurgence on the Web.**

Visiting a Text Site or Two

Media Architecture

- Strategic vision of media re-use
 - ***Multi-modal***
 - ***Multi-channel***
- Tactical repository of intellectual capital
 - ***Data base***
 - ***Text***
 - ***Print***
 - ***Video***
 - ***Audio***
 - ***Composite products***

The Dual Challenge in Managing Media Architectures

- Managing these resources as reusable objects
- Managing the enterprise-wide processes of transposing *intellectual capital* into media objects.

Presentation Roadmap

Introduction

Commerce

Communication

Collaboration

Wrap-Up

**The
Organization**

Organizational Information Resources

Organizational Knowledge

The Intranet

**Network

Leaders of the Internet

The Internet in the Year 2010

John R. Patrick

Vice President, Internet Applications

IBM

The Internet in 2010: The Road to the Future

- ◆ Where We've Been
- ◆ Where We Are Today
- ◆ Where We're Headed.....
 - in Business
 - as a Society

Where We've Been

- ◆ From curiosity to media darling
- ◆ From grassroots to corporate boardrooms
- ◆ “Get connected”

“Get connected”

- ◆ Email@GetCo.com
- ◆ Directory_assistance@GetCo.com
- ◆ Experts_and_executives @GetCo.com
- ◆ Info @GetCo.com
- ◆ WWW @GetCo.com
- ◆ Sales_and_services @GetCo.com

<http://www.ibm.com/patrick>

Where We Are Today

- ◆ Education Continues
 - The Net as mainstream I/T
 - TCP/IP as extension
 - Massive disintermediation
 - Bandwidth
- ◆ Issues not yet framed for resolution
 - Security, Encryption and Privacy
 - Content rating

Where Business is Headed

- ◆ One global Internet integrated with legacy
- ◆ Global security well understood & managed
- ◆ Open standards predominant-IP everywhere
- ◆ E-commerce a very large market segment
- ◆ Software reuse enabling market driven I/T
- ◆ “Get connected” enabling complete access
- ◆ Responsive, agile companies prospering

Where Society is Headed

- ◆ Encryption and authentication taken for granted and trusted
- ◆ Public Access to the Web
- ◆ Bandwidth not a limitation - agents to help
- ◆ Physical communities based on lifestyle
- ◆ Geoindependent work and collaboration
- ◆ Internet as cultural, economic equalizer

The Future is Now!

- ◆ Unlimited reach for businesses and organizations
- ◆ Unlimited choice for individuals
- ◆ It is up to you and I
- ◆ Let's go for it and “Get connected”!

COMPUTER CRIME

**Kenneth Rosenthal, Esq.
Brenner, Saltzman & Wallman
New Haven, Connecticut**

I. Federal Criminal Provision Governing Unauthorized Computer Access

A. 18 U.S.C. §1030 (Computer Fraud and Abuse Act) -- Prohibits unauthorized access to computer system, through means of a computer used in interstate commerce, with intent to damage or withhold use of computer, program or data, provided there is loss or damage in the aggregate amount of \$1,000 or more during any one year period; unauthorized access to federal government, financial institution or credit reporting agency computer data; or trafficking in passwords or similar computer access information. Penalties include fines or jail terms of up to twenty years.

B. 18 U.S.C. §2701 (a part of E.C.P.A., which primarily deals with wiretapping and prohibitions against interception and disclosure of electronic communications, as described in Part IV, below) -- also provides criminal penalties for obtaining, altering or preventing access to electronic communications while in electronic storage through unauthorized access to an electronic communication service. Unlike CFAA, there is no minimum damage requirement, but the penalties are far less severe than under CFAA, with jail terms of six months to two years.

II. State Computer Crime Statutes

Varying statutory provisions establishing criminal liability for, inter alia, unauthorized access to use of a computer system, intentionally altering or destroying computer data or program, theft of computer services, unlawful possession of computer-related materials, destruction of computer equipment and fraudulently obtaining commercial computer services. Some statutes also provide civil causes of action for damages, injunctive relief and attorneys' fees. The **attached chart** provides citations to the 50 state laws with an analysis of the types of offenses covered in each state.

III. Other Criminal Statutes Used in Recent Prosecutions of Internet Activity

1. 18 U.S.C. §1343 (Wire Fraud) -- An extremely broad statute penalizing the transmission of a wire communications in interstate commerce in furtherance of any scheme to defraud or to obtain money or property by means of false or fraudulent pretenses.

2. 18 U.S.C. §875(c) (Interstate Communication of a Threat) -- Penalizing the communication of any threat to injure the person of another. Unlike most state harassment statutes, this federal statute does not require that the threat have been communicated to the victim. A federal district judge in Michigan recently dismissed the highly-publicized prosecution of an University of Michigan undergraduate for the transmission of E-mail messages under this statute. See United States v. Baker, 890 F. Supp. 1379 (E.D. Mich. 1995).

3. State Harassment Statutes -- These laws typically include mischievous use of wire communications to harass another person, whether or not a "conversation" takes place -- e.g. prank calls including, but not limited to, abusive language. There are also some statutes specifically directed at E-mail harassment. One recently publicized example is contained in

Section 53a-182b of the Connecticut General Statutes, as amended in June 1995, to include intentionally harassing threats communicated by computer network, and the transmission of intentionally harassing indecent or obscene language by computer network. For an analysis of the need for such statutes to supplement existing harassment statutes, see Note, *Taking a Byte Out of Crime: E-Mail Harassment and the Inefficacy of Existing Law*, 70 Washington Law Review, 465 (1995).

IV. Electronic Communications Privacy Act, 18 U.S.C. §2510 et. seq.

E.C.P.A. amended the federal wiretap statute to encompass electronic communications. It governs the interception and disclosure of in-transit electronic communications (Title I), and access and disclosure of electronic communications while in electronic storage (Title II). The proscription against interception of live communications are far more stringent than those with respect to accessing communications in “electronic storage”. Stored communications may regularly be accessed by the operator of an electronic communications service. In-transit communications, on the other hand, may only be intercepted under limited circumstances. In the case of the systems operator, such circumstances include interception by the operator’s

officer, employee, or agent . . . in the normal course of his employment while engaged in any activity which is a necessary incident to the rendition of his service or to the protection of the rights or property of the provider of that service, except that a provider of wire communication service to the public shall not utilize service observing or random monitoring except for mechanical or service quality control checks.

18 U.S.C. §2511(2)(a)(i)

There is a further exception permitting interception by any person of “an electronic communication made through an electronic communication system that is configured so that such electronic communication is readily accessible to the general public.” *Id.* §2511(2)(g)(1). In other words, the prohibition against interception does not apply at all to such publicly accessible communication as those involved in public Usenet groups.

The distinction between in-transit communications and communications in electronic storage is somewhat slippery, but seems to err on the side of defining virtually all electronic communications as “stored communications” except at the moment when actually in transmission. The statute defines electronic storage as (A) any temporary, intermediate storage of an electronic communication incidental to electronic transmission, and (B) storage of such communication by an electronic communication service for purposes of backup protection. 18 U.S.C. §2510(17). Commentators have noted that the legislative history of the statute suggests that the term electronic storage even encompasses storage in RAM. Similarly, the Court in Stephen Jackson Games, Inc. v. U.S. Secret Service, 36 F. 3d 457 (5th Cir. 1994), while awarding the system’s operator damages against the Government for seizure of his computer system under the applicable provisions of Title II, held that Title I (providing more substantial damages) was not violated despite the fact that a large number of undelivered E-mail messages were included in the seized materials. The Court based its conclusion on the statute’s broad interpretation of electronic storage and correspondingly narrow interpretation of electronic communications in-transit.

E.C.P.A. prohibits unauthorized disclosure of the contents of electronic communications, whether stored or in transit, unless certain exceptions are satisfied. In other words, the privacy of E-mail communications, even while in temporary “storage”, is protected from disclosure

regardless of whether it is protected from access by systems operators. Among the exceptions to the bar on disclosure, there are exceptions in the case of a systems operator making disclosure to intended recipients of the communication, disclosure to persons to whom disclosure is necessary as an incident to the rendition of the services being performed, disclosure necessary to the protection of the rights or property of the provider of the service, and disclosure to a law enforcement agency of the contents of an electronic communication which appears to pertain to the commission of a crime, provided in the latter instance that the service provider had inadvertently come upon the contents of such communication in the first place. A service provider is also expressly protected from liability for disclosure pursuant to a court issued wiretap order or subpoena.

Interception and disclosure prohibitions do not apply where one party to the communication consents. Thus, if the service provider is itself a party to the communication, or if some other party to the communication discloses it or authorizes interception, the prohibitions of E.C.P.A. would not apply.

IV. Responding to Search Warrants and Subpoenas.

As the Stephen Jackson Games (SJG) case graphically illustrates, the execution of a search warrant on an innocent business enterprise which may happen to be in unknowing possession of evidence of a crime (or of what law enforcement suspects may be a crime) can be disruptive in the extreme. In the SJG case, federal agents pursuing the prosecution in Chicago of individuals involved in the copying of a telephone company document relating to the E 911 system, obtained a search warrant for the Austin, Texas premises of Stephen Jackson Games, the publisher of various books, magazines and games, and the operator of a BBS used in conjunction with its business. The warrant authorized the federal agents to seize:

[c]omputer hardware . . . and computer software . . .
and . . . documents relating to the use of the computer
system . . ., and financial documents and licensing
documents relative to the computer programs and
equipment at . . . [SJG] . . . which constitute evidence
. . . of federal crimes . . . This warrant is for the
seizure of the above described computer and
computer data and for the authorization to read
information stored and contained on the above
described computer and computer data.

In executing the warrant, the federal agents seized the entire computer system used to operate the BBS, containing more than 100 items of undelivered private E-mail, various work in progress essential to SJG's publishing business and other unrelated hardware and software, including laser printers which could not conceivably have contained anything of relevance to the investigation. Despite the entreaties of legal counsel and contacts with political representatives, it was not until four months later that SJG was able to obtain return of the equipment, and substantial damages were incurred as a result of the disruption of its business.

The Fourth Amendment to the United States Constitution protects one's person, houses, papers and effects from unreasonable search and seizure, and provides that a warrant can only issue upon a finding of probable cause by a neutral magistrate based upon a factual submission under oath, stating with particularity the place to be searched and the items to be seized. The reality is that hundreds of thousands of search warrants are issued in the course of each year and the scrutiny with which they are addressed in the initial instance is often minimal. As the SJG case illustrates, it is only after the fact -- after the damage has been done -- that a person subject to search can have any input whatsoever as to the scope or reasonableness of the search and seizure in question. After a particularly egregious instance of third party search of the Stamford University Daily had been upheld by the United States Supreme Court some decades ago, Congress enacted legislation to provide special additional protection in the case of publishers, and the Justice Department now has guidelines limiting the instances and manner in which search warrants will be sought in such cases. Many states have similar statutes. However, as the Stephen Jackson Games case once again illustrates, these protections are not necessarily effective. It should be noted that unlike most bulletin board operators, Stephen Jackson Games enjoyed the protected status of a traditional publisher, but nevertheless suffered the consequences of an overbroad unannounced search.

What can one do in the face of a search warrant? First of all, the search warrant may very often be executed with no advance notice. Second, no matter what one may think of the search warrant at the time of its execution, it is a crime to interfere with the execution of a search warrant. At the same time, reasonable efforts can be made to persuade the executing officers that one will fully cooperate in the search and, in return, hopefully acquire some opportunity to inject informed reason into the search process based on knowledge of the computer system that the executing officers are not likely to have. At the same time, if at all possible, one should get legal counsel involved and on the scene.

If, instead of a search warrant, the government chooses to proceed by subpoena, there is automatically an opportunity to have legal counsel involved, to contact the federal agents and the United States Attorney identified on the subpoena and, if negotiations concerning the scope of the subpoena do not produce satisfactory results in advance of the deadline for responding, to get into court to move to limit or quash the subpoena. Moreover, along with advance notice and an opportunity to be heard, the subpoena carries the additional advantage that the system's operator himself, rather than some law enforcement official will be the one to gather and turn over the

requested evidence -- a distinction of special importance in the case of evidentiary seizures directed at computer systems by law enforcement officials unschooled in the subtleties of computer hardware and software, to say nothing of the networks that tie them together. Further, there may be an opportunity to negotiate the use of duplicate copies of requested materials without disruption or loss of use of the items in question for operating purposes. Indeed, E.C.P.A. makes express provisions for such backup copying in the case of subpoenas for evidence issued pursuant to its provisions, complete with provisions for reimbursement of the owner of the searched facilities for the costs of searching, assembling, reproducing or otherwise providing information to the government in connection with duly issued court orders and subpoenas. See 18 U.S.C. §2706.

Presentation

Editor's Note: While many Internet access providers use operating systems other than UNIX, it is the most widely used system on the Internet. Even non-UNIX systems frequently use UNIX-like commands. Many of the basic commands discussed in this article will be applicable to whatever system you have.

As you explore the Internet, chances are that you will use or dial into a computer system that works with the UNIX operating system. If you're only familiar with DOS or Macintosh computers, trying to use UNIX can make you feel like a stranger in a strange land.

UNIX is the most popular operating system on the Internet because it is available for a wide variety of computer platforms and has a multi-user, multi-tasking environment. This means that several people can use a UNIX computer simultaneously—and each person can run several programs at once.

UNIX

Learning the

BY KEVIN M. SAVETZ

The system was developed in 1969 at the Bell Laboratories. Since its creation, UNIX has seen countless updates, revisions and spinoffs. Today, there are flavors of UNIX with names like SCO UNIX, BSD and System V. These versions are very similar, but it is important to know what one you're using when you have a question or are looking for a book on UNIX.

Here's the basic information you will need to use UNIX. With practice you will be able to combine commands to easily perform otherwise complex tasks.

Paul J. Fisch

Language of the Internet.....

LOGGING IN AND OUT

To access a UNIX system, you'll need the system administrator to set up your own account. When you want to get on the system, you enter your account name and a secret password. (For more on passwords, see "10 Things Not To Use As Your Password.") The computer uses this information to verify who you are, give you access to the information that belongs to you and keep other users out of your files. If you're legit, you'll see the UNIX prompt, your signal that the computer is ready to take a command.

If you use DOS, you're familiar with a prompt like (C:\>). UNIX prompts vary from system to system, but it is likely to be a dollar sign (\$) or a percentage sign (%).

When you log on, you may also see the system "message of the day" (or MOTD, pronounced mot-dee) announcing

anything the system administrator thinks you need to know. You may also see a message if you have any unread electronic mail.

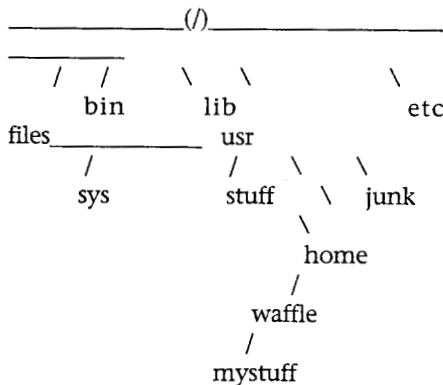

To log off the system, simply type `logout`. This is important because it tells the computer you don't plan on using it for a while and will prevent others from looking through your files.

FILES AND DIRECTORIES

If you've used another computer operating system, you are already familiar with the concepts of files and directories. Files are individual collections of information (a letter to Aunt Zelda, a picture of the moon or a game's software) stored on a computer. Directories allow you to place files in a logical manner so you can find them later. UNIX files and

directories are very similar to those on DOS computers.

Your account has a **home directory**, which is where you start by default when you log on to the system. You can change your current directory, list its contents, create new directories and remove ones that are part of your home directory. Like DOS, UNIX uses a hierarchical directory structure. This means that there is one **root directory**, and many sub-directories in which you can store files. A diagram of the structure might look like the following:

A file in the **mystuff** directory can be referred to as **/files/home/waffle/mystuff/filename**.

This is the filename's full path. The first **/** must be there for it to be a full path. If you leave it off, UNIX will look for the file starting in the your present directory. (Leaving off the **/** can be use-

ful because constantly referring to files by their full pathnames gets tedious. If you were in **waffle** and wanted to refer to **filename** in the **mystuff** directory, you could call it **mystuff/filename**. If you are already in **mystuff**, just use **filename**.)

If you use DOS on your home computer, note that UNIX uses a forward slash (**/**) between directory names instead of a backslash (****).

If you use DOS, you're also used to restrictive filenames with eight letters, a period and an extender of three more letters (for example, **GRANDMAS.LTR**). If you use a Macintosh, you have the luxury of filenames of up to 31 characters. Depending on what flavor of UNIX you're using, you may be allowed filenames from 14 to 255 characters. Unlike DOS—which only allows A thru Z, 0 thru 9 and the underline in filenames—UNIX filenames can contain just about any character you can type on the keyboard. (Some characters—the asterisk, brackets and spaces—can be used, but can also get you in sticky situations later. It's best to avoid using them.)

BASIC UNIX COMMANDS

Below are some important commands for manipulating files and directories. The first rule of UNIX: Use and love the **man** (manual) command. Typ-

ing **man cp**, for instance, will tell you everything you could want to know about the **cp** command. Type **man man** and **man intro** for general system help. Most of the following commands take special options, called arguments, for tweaking how they work. There isn't room here to list each command's options and arguments, so make judicious use of the **man** command.

pwd - Stands for "present working directory," and it will tell you in which directory you currently are. Log on to your system and type **pwd** to find out what your home directory is called.

ls - Lists all the files and directories under your present working directory. One problem: The **ls** command doesn't tell you whether you're looking at the names of files or directories. Not to worry—if you type **ls -CF**, you'll get a nicely formatted list where executable files (programs) are indicated with an asterisk and directories by a slash.

Some files in UNIX are normally invisible (hidden) files. Any filename that begins with a period—such as **.newsrc** and **.login**—isn't normally shown when you enter the **ls** command. You can see them, however, if you explicitly ask to see all files by adding the **a** argument to the **ls** command: type **ls -a** or **ls -aCF** (yes, capitalization matters!) to see your invisible files. Invisible files usually specify your system configuration—or, perhaps you simply have something to hide.

cd - Stands for change directory. You can move to a subdirectory under your present directory by typing, for example, **cd mystuff**. To move back to the previous one, type **cd ..** (That's two dots. Why two dots? It's a mystery to me.) If you know exactly what directory you want to go to, you can type a command like **cd /lib/sys**.

cp - Is an abbreviation for copy. Not surprisingly, the **cp** command lets you copy a file. Typing **cp file1 file2** will create a new copy of **file1**, called **file2**, in your present directory. Typing **cp file1/files/home/wombat** will put a copy of **file1**, still called **file1**, in the **files/home/wombat** directory. Typing **cp file1/files/home/wombat//file2** will make a copy of

UNIX VS DOS

Here are some important ways in which UNIX differs from DOS.

The DOS prompt looks like **c:\>**

The UNIX prompt looks like **\$** or **%**

DOS uses backslashes ****

UNIX uses forward slashes **/**

DOS filenames are restricted to eight letters, a period and an extension of three more letters (**GRANDMAS.LTR**)

UNIX filenames can range from 14 to 255 characters.

DOS filenames can consist only of the letters A thru Z, the numbers 0 thru 9 and the underline character.

UNIX filenames can contain just about any keyboard character.

• In UNIX, there is no "undelete" command. Once your file is gone, it's gone forever.

file1, called *file2*, in */files/home/wombat*. Whew!

mv - Is an abbreviation for move, and lets you move files around directories. Moving a file will copy that file to your specified directory and then delete the original.

rm - Stands for remove. This command will let you erase files that you no longer need. Be careful! There is no "undelete" command in UNIX. Once your file is gone, it's gone forever.

Typing **rm file2** will erase that file from your present directory. Typing **rm*** will delete every file in the directory. In UNIX, like in DOS, the asterisk means "all files".

cat - Stands for catenate, an obscure word meaning "to form a chain or series." In its most basic use, cat works just like the DOS TYPE command; it displays the contents of a text file. Actually, you can use it to display the contents of any file, but binary files (like programs and digitized pictures) will only appear as garbled data. To display a file, just type **cat letter_to_grandma** and the computer will print the letter to your screen. If the text in the file is too long, the beginning will scroll off the top of the screen faster than you can read it. Which brings us to the next command...

more - Shows you the contents of a text file one page at a time. If you type **more letter_to_grandma**, you'll see the word "more" after each screen of text. Strike the space bar when you're ready to see the next page of text. Your system may also have a program called **less**, which does the same as more, only better. As they say, less is more. :) Don't forget to type **man less** or **man more** for complete information or more options.

chmod - Can be used to change the permissions of a file, or those users who have access to a particular file. Remember that UNIX is a timesharing system that can be used by many people simultaneously. You might want to keep some of your files - for instance, your electronic mail - private, but let other users read or modify certain files. So **chmod**, which stands for "change mode," makes it possible to allow/deny yourself, all system users or only certain

users to read, write or execute your files. For more information (you saw this coming, right?) type **man chmod**.

MISCELLANEOUS COMMANDS

Here are some other commands that are important, but don't really fit in with other groups.

man - OK, I already mentioned this one, but I'm mentioning it again to make sure you know how to RTFM (read the manual). The **man** command shows you the "manual page" for a particular command. For instance, **man ls** will give you lots of information about the **ls** command.

vi or **emacs** - Are text editors or programs that allow you to create text files (such as e-mail messages, programs or letters to Aunt Zelda). If you're just starting out, try using "vi." It's not the simplest text editor available, but it's easier than emacs. In contrast, emacs is

a software behemoth that will edit files, tell your fortune and teach you how to make cookies. (Really.)

lpr or **print** - May let you print a text file on a printer connected to the UNIX computer. Two caveats: First, never try to print a non-text file—anything that looks like gibberish when viewed onscreen with the **cat** command will look worse on paper. Second, if you're working from a college computer lab or your office and know there's a printer down the hall, feel free to use the **print** command. However, if you're using a dial-up UNIX system—and the main terminal is hundreds of miles away—don't use the printer unless you intend to drive there to pick up your printout!

grep - Stands for "global regular expression print," which is a verbose way of saying that this program will search through files and output any lines that containing text you specify. If you've ever read Usenet news, your home directory contains a hidden file called **.newsr** which lists all the newsgroups available to you. Typing **grep**

Buy all your books on-line!

Visit Book Stacks Unlimited, the on-line bookstore and reader's conference system with over 265,000 titles. You can search for books by author, title, keyword or ISBN, or just browse the 'shelves' by subject. Choose your titles, place your order, and we will ship your books directly to your home or office.

If you are a corporate buyer or librarian, we have special services and payment plans to make your job easier. For more information, please contact Camille Heritage at (216)861-0467.

`amiga.newsarc` will list all the lines in the file that contain the word "amiga."

`passwd` - Allows you to change your password. Typing `passwd` will prompt you for your old password then ask you to type your new password twice. Passwords you type should never be visible on your screen.

`compress` and `uncompress` - Are a pair of programs that will compress or decompress the file (or files) of your choice. Compressed files end in the extension ".Z" and take up less disk space than uncompressed ones. Many of the files available via the Internet's ftp program are compressed to save space and reduce transfer time. Similar to .zip files on a DOS computer and .sit files on a Macintosh, UNIX's compressed files take up relatively little space. But, they aren't useful until they've been uncompressed. To use these commands, just type `compress filename` or `uncompress file name.Z`.

FOR MORE INFORMATION

This article has just given you enough information about UNIX to be dangerous. UNIX is a complex operating system made up of hundreds of commands, oddball nomenclature and countless little quirks. Don't worry—the Internet is rife with beginner's information about UNIX. To explore more of the basics, check out one of the following:

- The UNIX Frequently Asked Questions list. This huge, seven-part list of questions and answers explores the ins and outs of UNIX. Users of all knowledge levels will learn something from this file. It is available via FTP as `rtfm.mit.edu:/pub/usenet/news.answers/unix-faq/faq/part1` (as well as part2 through part7.)
- The `comp.unix.user-friendly` Frequently Asked Questions (FAQ) list, available via anonymous FTP from `ftp.wfu.edu:/pub/usenet/cuuf-faq`.
- A Concise Guide to UNIX Books. This lists contains selections of the best books and documentation on UNIX

and related subjects (such as UNIX editors and shells.) It's obtainable via anonymous ftp from `rtfm.mit.edu:/pub/usenet/news.answers/books/unix`. If you do not have FTP access you can get it by sending e-mail to `mail-server@rtfm.mit.edu` with a message body of `send usenet/news.answers/books/unix`.

- The Usenet newsgroups `comp.unix.user-friendly`, `comp.unix.questions`, `comp.unix.shell` and `news.answers`

If you prefer learning from traditional books, rent a forklift for your return trip from the library or bookstore. Dozens of fine UNIX books abound. Be sure that the book you pick is tuned to the version of UNIX you use (for instance, System 7 or BSD.) If you're not sure which book to read, start with one of these:

- *Learning the UNIX Operating System*, 3rd edition, by Grace Todino, et al. Published by O'Reilly & Associates, ISBN 1-56592-060-0. An introduction to UNIX, including information on electronic mail, networking and X-Windows. Geared toward users who need to better understand UNIX to make the most of the Internet.

- *UNIX for Dummies* by John Levine and Margaret Levine Young. Published by IDG, ISBN: 0-878058-58-4. An informal and non-technical introduction to UNIX.

- *Exploring the UNIX System*, 2nd edition, by Stephen Kochan and Patrick Wood. Published by Hayden books. ISBN: 0-672-48447-1. A basic overview of UNIX structure and commands from the ground up. (This was my first UNIX book.)

- *A Student's Guide to UNIX* by Harley Hahn. Published by McGraw Hill. ISBN: 0-07-025511-3. In a clear and lively language, the author tells novice users everything they need to know about UNIX and the Internet. The book covers commands, utilities, shells, vi, X-Windows, e-mail, and other topics.

- *UNIX in a Nutshell* by Daniel Gilly. Published by O'Reilly & Associates. ISBN: 1-56592-001-5. A complete reference guide containing all UNIX com-

mands and options, along with lots of examples and descriptions of the commands. Versions for System V releases 3 and 4 and Solaris 2.0, SCO UNIX and BSD systems are available. ■

10 THINGS NOT TO USE AS YOUR PASSWORD

On any Internet system, not just UNIX, your password is the only thing standing between you and disaster. If someone should guess your password, he or she will be able to read your electronic mail, snoop in your files, delete your work and post electronic mail or Usenet news messages that will appear to come from you. That can be embarrassing, annoying and dangerous.

UNIX systems use a tricky feature called one-way password encryption. When you first choose a new password, the computer encrypts your password—so thoroughly that it can never be decrypted—and only stores the encrypted version. Later, when you type your password while logging in, the computer encrypts your guess using the same method and compares the encrypted version of your guess to the encrypted version of your actual password. If they match, you're allowed in.

Although your password can't be decrypted, you're never perfectly safe. Unscrupulous crackers can use the encryption routine to stab guesses at your password. At least one computer program is available that can quickly and silently encrypt every word in the dictionary and compare it to the list of encrypted passwords on your system. Therefore, if your password is in the dictionary, you can get zapped.

A variety of other passwords that aren't in the dictionary are also bad choices because they're very easy to guess. The following is a partial list of words that should not be used as passwords.

- password
- opensaysme
- letmein
- your initials
- your login name
- your cat's name
- your spouse's name
- any information that can be found by looking up your account name on the system, such as your phone number, name, etc.
- any word that's in the dictionary

To be as safe as possible, make your password a bunch of unrelated characters, such as `K#*2ww>`. Use a combination of upper and lower case letters, punctuation and numbers. If you find this type of password too hard to remember, try using two unrelated words separated by a punctuation mark, like `explore*grasshopper`.

Kevin Savetz is a computer journalist based in Arcata, California. He believes that UNIX is more afraid of you than you are of it. Kevin can be reached via e-mail at `savetz@rahul.net` (Internet) and Savetz on America Online.

Macintosh Toolbox

THESE GEMS WILL GIVE
YOUR NET LIFE A LIFT.
BY KEVIN SAVETZ

The hard disk of my Macintosh is overflowing, but I can't complain because I'm the only one to blame. For instance, take my Internet folder (please!). This little trove of tools that work with my SLIP and PPP Internet connections weighs in at just over 20MB. Yow!

Macintosh users probably are familiar with most of the software that resides in that directory. There's the freeware version of Eudora, Mosaic, NSCA Telnet, TurboGopher, Fetch, and a variety of other essential wares. I consider these the staples of Macintosh Internet connectivity. These tools provide the basic functions you need to send e-mail, obtain files, and access Gopher and the World-Wide Web.

My toolbox, however, runneth over. The sheer bulk of my Internet directory betrays the secret that my computer harbors more than these essential Internet tools. Those 20MB hold some unique, almost magical tools that make my life on the Internet so much the better. These programs are just as wonderful as the Big Five tools listed above, but are perhaps

only less known, or for some unfathomable reason, less popular (at least, so far).

So I've filtered through the goodies in my Internet toolbox and will share with you some of the tools that you may not have used but should definitely try. Perhaps you've gotten along just fine without any of these programs

for months. Maybe you didn't think that something as simple as sending e-mail or grabbing a file from an anonymous FTP archive could be any simpler. But these programs do it better. Or possibly one of these tools does a task that you never really considered. Check out these programs. If you like enough of them, your Internet folder too can top 20MB.

Anarchie

Move over, Fetch, Anarchie is here. Anarchie (pronounced "anarchy") is one of the best ideas I've seen yet in an Internet tool. I can't believe someone didn't think of this long ago. Anarchie effortlessly combines the functions of FTP (the Internet's tool for

moving files around the Net) and Archie (a tool that finds programs available via FTP). These are normally two separate functions, but they are blended seamlessly with this program.

Simply type in the name of a program and Anarchie will find it for you using one of two dozen Archie servers. The next part is the real magic: When Anarchie presents

Archie

ANARCHIE MERGES SEARCH AND DOWNLOAD FUNCTIONS.

a list of hits, just double-click on one of them and it will FTP that file right to your machine—and automatically decompress for you. It sure beats the old two-step process of doing an Archie search, then (once you find the object of your desire) initiating an FTP session. Anarchie is instant gratification, or as close as I can get with my 14.4 Kbps modem.

In addition, Anarchie is fully compatible with AppleScript, which is great for automating FTP transactions. If you use System 7.5, you can take advantage of its extra features, including a detailed Apple Guide.

Anarchie is shareware (\$10) available via FTP from all the usual suspects—er, sites—like aim.stanford.edu and mac.archive.umich.edu. You also can find it at nic.switch.ch/mac/software/peterlewis/, amug.org/pub/peterlewis/, and redback.cs.uwa.edu.au/others/peterlewis/.

Maven

Maven has my vote for the Internet tool with the most potential to change how we use the Internet. Remember how Mosaic changed the way people used the Net? I predict that, in time, Maven could be the next killer app of the Internet. Not because it delivers elegant color graphics to your screen (it doesn't), but because it could one day nullify your long-distance telephone bill.

Maven is an audioconferencing tool that transmits sound over the Internet. That's right, you can plug a microphone into your Mac and chat away with people hundreds of miles away. Of course, there's a catch: Maven is a bandwidth hog. Even in its lowest-quality sampling mode, it still requires just a little bit more bandwidth than a 28.8 Kbps modem can give you. If your office has a 56 Kbps connection, you might try hogging most of that with Maven. If your mom in Cleveland has a similar Internet connection, you might be able to talk to her for free.

Maven can talk to other Macs running Maven, as well as the Unix Vat audio program. Maven's creator is working on adding better compression algorithms to the program, which means that perhaps soon Maven audio will require less bandwidth to work effectively. You

MACWEATHER SPORTS EASY-TO-READ GRAPHICS.

can get Maven via FTP in k12.cnidr.org/pub/Mac. Until, of course, AT&T finds out about this.

MacWeather

If you've been on the Internet for longer than 20 minutes, you've probably heard of the University of Michigan's Weather Underground, a tool for getting info about the current weather and forecasts. MacWeather puts a new face on the Weather Underground, using (rather than plain text) graphical weather symbols we're familiar with, like an on-screen barometer, thermometer, and weather vane. When you start up MacWeather, it

quickly tells you the weather in your favorite city. And it's easy to point at any of dozens of cities for a quick look at what Mother Nature has in store.

For cities in the United States and Canada, local forecasts are automatically downloaded along with the current weather conditions. Near-shore marine forecasts are available for coastal United States cities, as is climate data. MacWeather is available via FTP at mac.archive.umich.edu and aim.stanford.edu.

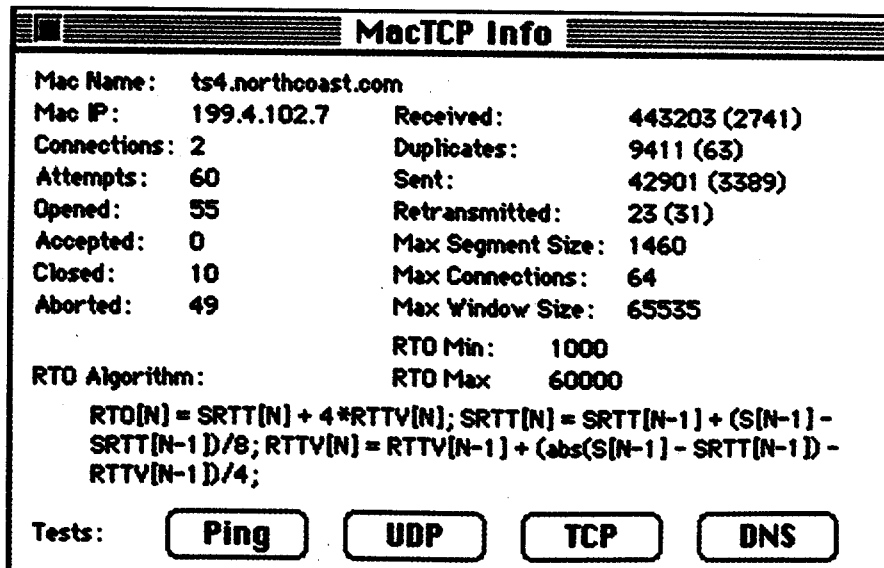

MacTCP Watcher

Although it's not the sexiest program out there—I mean, it won't fold your laundry, sort your files, or mix drinks—MacTCP Watcher gets my vote for best troubleshooting tool. Written by the same fellow

who brought us Anarchie, MacTCP Watcher can tell you how your Mac is passing packets, help you ping other machines on the Net, and test your domain name server.

To obtain assorted Macintosh tools, FTP to :

- ftp.ncsa.uiuc.edu
- ftp.tidbits.com
- ftp.tidbits.com/pub/tidbits/tisk
- ftp.tidbits.com/pub/eudora
- boombox.micro.umn.edu
- mrcnext.cso.uiuc.edu/pub/info-mac/comm/MacTCP
- wardrive.wustl.edu/systems/mac/umich.edu/wtl/comm

MACTCP WATCHER DOES EVERYTHING BUT CHECK OIL.

MacTCP Watcher displays the internal data of MacTCP operations. It shows the Mac's IP address, DNS name, and all the other information that MacTCP provides. It will also list all of your open TCP connections and information about each of them. It's excellent at reporting problems. For instance, if reverse domain-name lookup isn't working (an obscure but annoying problem), MacTCP Watcher will tell you about it. The program is useful if you are having MacTCP configuration troubles or are just (as the author is) chronically curious.

You can find MacTCP Watcher via FTP at [nic.switch.ch /mac/software/peterlewis/](ftp://nic.switch.ch/mac/software/peterlewis/), [amug.org /pub/peterlewis/](ftp://amug.org/pub/peterlewis/), and [redback.cs.uwa.edu.au/others/peterlewis/](ftp://redback.cs.uwa.edu.au/others/peterlewis/).

Eudora

Eudora is hardly an obscure program. On the contrary, I'm willing to bet it's the single most popular mail program for the Mac (and Windows). But perhaps you were not aware that there are two versions of Eudora—a free version and the commercial one. If you did know this, perhaps you haven't considered shelling out money for something you already have for free. I didn't think that the free Eudora could be improved, but the commercial version offers a variety of strong features that are definitely worth the cash you would shell out.

My favorite feature by far is Eudora's ability to spell-check e-mail before I send it. I quiver at the thought of what my messages must have looked like before I started using the new Eudora. It has caught dozens of typos that would have otherwise gone unnoticed by me (but would likely have been noticed by my correspondents).

APPLE PICKS SOME WINNERS

On September 30, Apple Computer gave awards to eleven individuals and organizations whom it deemed critical players in creating a wide variety of Internet tools for the Macintosh. Each of the following winners of the Cool Tools award (yes, that's really what it's called) received a certificate and a PowerMac 7100:

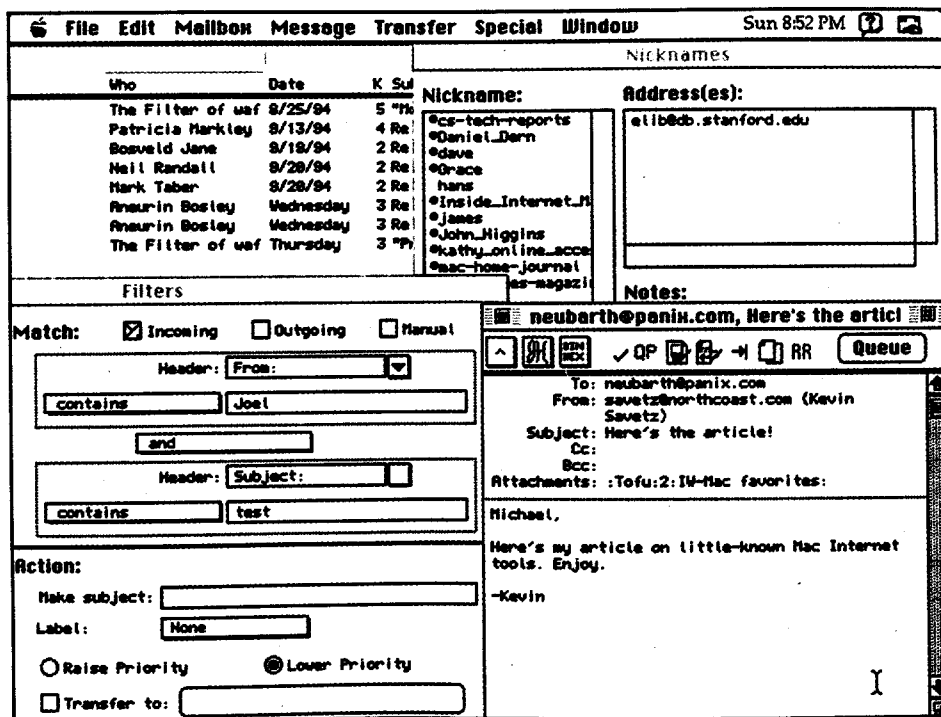

- The Internet Society of Reston Virginia (for its overall contribution).
- Steve Dorner of QUALCOMM (for Eudora).
- Chuck Shotton from Houston, Texas (for MacHTTP, a World-Wide Web server).
- Peter Lewis of Perth, Australia (for FTPd and Anarchie).
- The University of Michigan, Weather Underground (for Blue-Skies).
- John Hardin of EInet, Austin, Texas (for MacWeb).
- National Center for Supercomputer Applications in Urbana, Illinois (for Mosaic).
- Aaron Giles of Cornell University Medical College, New York (for JPEGView).
- John Norstad of Northwestern University, Evanston, Illinois (for Newswatcher).
- Cornell University, Ithaca, New York (for CU-SeeMe).
- University of Minnesota at Minneapolis, MN (for TurboGopher, a gopher browser, and GopherSurfer, a gopher server).

Eudora 2.1 can automatically encode and decode BinHex and uuencoded binary files. It can handle return receipts and has a snazzy tool for filtering your messages (for example, by automatically moving mail from a high-volume mailing list to a special folder, or marking messages

from your sweetheart in red letters). It handles multiple signatures, expanded nickname functions (for quickly sending one message to a group of people), and too many other nice tweaks to mention here. Executive summary: It's a winner.

Eudora from Qualcomm is \$65 (\$99 with the spell-checker option). You can get information via FTP (and pick up the free version of Eudora) at [ftp.qualcomm.com](ftp://ftp.qualcomm.com), or call Qualcomm at 800-2-EUDORA.

Kevin Savetz (savetz@northcoast.com) is author of *Your Internet Consultant—the FAQs of Life Online* (Sams Publishing, 1994) and co-author of *Internet Press, a free guide to on-line journals about the Internet*. For a copy, send e-mail to savetz@northcoast.com with "send ipress" in the subject line.

EUDORA'S MULTIPLE FEATURES MAKE E-MAIL A BREEZE.

FALL INTERNET WORLD

MACINTOSH INTERNET TOOLS

SOURCES

Current versions of most of these applications are available for downloading via:

<http://www.northcoast.com/savetz/iwmactools.html>

Many of the applications whose source sites are listed here are also available in recent versions from <ftp://ftp.scs.unr.edu/pub/macintosh/tcp-connections>, the various Info-Mac mirror sites and from the Tidbits archive at <ftp://ftp.tidbits.com/pub/tidbits/select/>.

All the path information has been recently checked to be sure it's as accurate as possible, but changes occur frequently, so you may encounter variations.

Some, but not all, of these applications have "fat" binaries, or native versions for PowerMacs. Many are free or have free versions. However, others are shareware or commercial software, and you should consider registering if you use a copy on a regular basis.

TELNET

The basic Internet tool that lets you connect and login to remote computers from your desktop. Free from the National Center for Supercomputing Applications. A new beta version of Telnet 2.7 is now available which supports drag and drop, and which has smoothed out some rough edges from earlier versions.

NCSA Telnet for Macintosh, Version 2.6 and 2.7b4 (Beta)

<http://www.ncsa.uiuc.edu/SDG/Software/Brochure/MacSoftDesc.html>

<ftp://ftp.ncsa.uiuc.edu/Mac/Telnet/Telnet2.7/>

FTP

FTP lets you place and retrieve software and files from remote computers. Fetch is easy to learn and use. Anarchie combines an FTP client with an Archie client, which helps you hunt down software and files across the net. Anarchie is shareware and comes with a comprehensive set of bookmarks for Internet software archives.

(FTP, Continued)

Fetch, Version 2.1.2 and 3.0b6 (Beta)

<ftp://ftp.dartmouth.edu/pub/mac>

Anarchie, Version 1.0.6

<ftp://cadadmin.cadlab.vt.edu/pub/peterlewis/>

E-MAIL

Eudora 1.5.3 is a freeware version of the commercially available POP (Post-Office-Protocol) client for e-mail, that lets you bring your Internet e-mail from your Internet provider down to read on your Mac.

Eudora, Version 1.5.3

<ftp://ftp.qualcomm.com/quest/mac/eudora/1.5/eudora153.hqx>

Claris Emailer is commercial software, but a demo version is available on the net. The big thing about Claris Emailer is that it can check email on Internet, AOL, eWorld, Compuserve and RadioMail.

Claris Emailer, Demo Version

<http://www.claris.com/Products/ClarisEmailer/index.html>

If you read your mail from more than one place, POP mail can be limiting. Mail Drop uses the more sophisticated IMAP protocol, which allows you to store and manipulate your mail on the remote mail host. This still has some rough edges, and is under development, but the advantages make it worthwhile, if IMAP is something you need.

Mail Drop Version 1.1

http://ackmo.baylor.edu/files/Mail_Drop/Mail_Drop.hqx

VideoMail is a marriage of multimedia and the Internet. It uses audio and video capturing equipment to produce QuickTime movies. These movies can then be sent to one or more people using Simple Mail Transfer Protocol (SMTP).

VideoMail Version 1.0

<http://www.spyglass.com/~dtrinka/videomail.html>

GOPHER

A classic Internet browsing tool, Turbogopher is speedy and reliable. The newest versions are aware of non-gopher protocols and can hand off information to other clients, including World Wide Web browsers. A 3-D version is in development but is still highly experimental. As the developers themselves say, "use at your own risk."

TurboGopher, Version 2.0

<ftp://boombox.micro.umn.edu/pub/gopher/Macintosh-TurboGopher>

Gopher VR, Version 2.1a4

<ftp://boombox.micro.umn.edu/pub/gopher/Macintosh-TurboGopher/TurboGopherVR/>

WAIS

A nice shareware implementation of a WAIS (Wide Area Information Service) client, MacWais helps make searching Internet databases easier. However, unreliability of the public servers can sometimes make this frustrating to use.

MacWais, Version 1.29

<ftp://ftp.einet.net/einet/mac/>

USENET NEWSREADERS

For keeping up on USENET newsgroups, there are several nifty newsreaders. Braddlee likes InterNews; Kevin is a fan of NewsWatcher.

InterNews, Version 1.1

<ftp://ftp.dartmouth.edu/pub/mac>

NewsWatcher, Version 2.0

<ftp://ftp.acns.nwu.edu/pub/newswatcher/>

Nuntius, Version 2.0.4

<ftp://frederik.ruc.dk/pub/nuntius/>

WORLD WIDE WEB BROWSERS

Netscape has taken the Internet by storm. Version 1.12 is commercial software which is free for individual evaluation and educational use. Mosaic, which helped to create the original wave of excitement over the Web, has a new completely free version available, but it's buggy and doesn't support some of the newer HTML codes. MacWeb works well in conjunction with TurboGopher and MacWais, but has simply not kept up.

NCSA Mosaic for Macintosh, Version 2.0.1
<http://www.ncsa.uiuc.edu/SDG/Software/MacMosaic/>

Netscape, Version 1.12
<http://www.netscape.com/comprod/mirror/mac/>

MacWeb, Version 1.1.1E
<ftp://ftp.einet.net/einet/mac/macweb>

IRC (INTERNET RELAY CHAT)

IRC is the ultimate network time killer; Homer is a IRC client *par excellence*. Easy to use, it's also a widget-lover's dream, even including support for the Speech Manager text-to-voice Mac extension.

Homer, Version .94
<ftp://mirrors.aol.com/pub/info-mac/comm/tcp/homer-094.hqx>

DESKTOP VIDEO

The availability of the Connectix Quickcam (a software-supported video camera for the Mac priced under \$100) has done a lot to increase the popularity of this new area of Internet exploration. Maven (below) is incorporated into recent versions of Cu-SeeMe, and will support audio for ethernet-connected Macs.

CU-SeeMe, Version 0.83b2
<http://cu-seeme.cornell.edu/>

DESKTOP AUDIO

Maven and Netphone are utility programs that allow you to transmit real-time audio over the Internet. Maven is now built-in to Cu-SeeMe, but is also available as a separate freeware program. Maven will not work over a dial-up connection. NetPhone is commercial software, available in a crippled demo version on the net, and will work over dial-up lines.

Maven, Version 2.0d23
<http://ux2.cso.uiuc.edu/~kline/>

Netphone, Version 1.2.3 (demo)
<http://www.emagic.com/>

RealAudio can be used as a stand-alone program or as a WWW helper application to support one-way client-server audio transmission. RealAudio can play back audio files on the fly, eliminating the long wait to download big audio files.

RealAudio
<http://www.realaudio.com>

PGP fone is the next wave in Philip Zimmerman's revolution to bring privacy to the masses. It uses sophisticated public-key encryption technology to provide secure phone conversations, in much the same way PGP does for electronic mail. Currently works with a modem and phone line -- an Internet version is coming soon.

PGPfone, Version 1.0b4 (beta)
<http://web.mit.edu/network/pgpfone>

WEATHER

MacWeather is a compact weather utility that provides useful weather info in an attractive package. Blue Skies goes more in-depth and is a modified gopher client, intended for teaching K-12 students about meteorology.

MacWeather, Version 2.0.4
<ftp://mojo.ots.utexas.edu/pub/mac/tcpip/>

Blue Skies, Version 1.1
<http://www.umich.edu:80/group/itd/archive/Public/html/mac/util/comm/gopher/>

NETWORK UTILITIES

Mac versions of the popular Unix/network tools. Internet Config is a step towards one-time setup of all your Internet applications, although support for it is far from universal. Finger allows you to check account information for Internet users, Fingerd allows your Mac to respond to finger requests. Talk supports a split screen chat session from your Mac to another Internet host, Talkd lets your Mac respond to requests to talk from other hosts. MacTCP Watcher is a collection of useful, albeit geeky, debugging tools, including Ping and DNS nameservice checking. MacTCP Switcher permits multiple IP's for Macs that travel between ethernet and PPP connections.

Internet Config, Version 1.1

<ftp://cadadmin.cadlab.vt.edu/pub/peterlewis/internet-config-11.hqx>

Finger/Fingerd, Version 1.3.7

<ftp://cadadmin.cadlab.vt.edu/pub/peterlewis/>

Talk/Talkd, Version 1.1.1

<ftp://cadadmin.cadlab.vt.edu/pub/peterlewis/>

MacTcp Watcher

<ftp://cadadmin.cadlab.vt.edu/pub/peterlewis/>

MacTCP Switcher

<ftp://mirrors.aol.com/pub/info-mac/comm/tcp/mactcp-switcher-11.hqx>

MacTcp Monitor

<ftp://mirrors.aol.com/pub/info-mac/comm/tcp/mactcp-monitor-10d30.hqx>

PGP

PGP is a freeware, public-key encryption program for the Mac and many other platforms. You can use it to safely encrypt e-mail and other files for secure transmission over the Internet. Because of export and license restrictions, it is not available except at net-dist ftp site at MIT. Be sure to read and follow the directions at the FTP site. The Mac version is comparatively easy to use, but still not painless.

(PGP, Continued)

PGP, Version 2.6.2

<http://web.mit.edu/network/pgp.html>

PPP/SLIP

PPP stands for Point-to-Point-Protocol, a neat system which allows you to run TCP/IP over conventional phone lines using a modem (14.4 bps or above is highly recommended). PPP has rapidly replaced SLIP, so if you have a choice, choose PPP. MacPPP was developed by Merit, Inc., in Ann Arbor, MI, and is freeware.

MacPPP, Version 2.1sd

<http://www.umich.edu:80/group/itd/archive/Public/html/mac/util/comm/>

SLIP stands for Serial Line Internet Protocol, an earlier version of the same sort of nifty trick that PPP also does. PPP offers somewhat greater security and efficiency than SLIP does, so if you have a choice, use PPP. InterSlip is commercial software, but demos are available via FTP from Intercon. MacSlip is another commercially available package, but is not available directly on the net.

InterSLIP, Version 1.0.1

<ftp://ftp.intercon.com:intercon/sales/InterSLIP/>

INTERNET SERVER SOFTWARE

Macs can make good to excellent Internet servers, depending on their use and how they are managed. Three of the most common uses are World Wide Web (MacHttp), Gopher (GopherSurfer) and FTP (FTPd)

MacHTTP, Version 2.2

http://www.biap.com/machttp/machttp_software.html

GopherSurfer

ftp://boombox.micro.umn.edu/pub/gopher/Mac_server/GopherSurfer1.1b3r2.sea.hqx

FTPd

<ftp://cadadmin.cadlab.vt.edu/pub/peterlewis/FTPd-300.sit>

That's all, folks!

***Real Time Internets for
Business and Entertainment***

Martin L. Schoffstall

Sr VP & CTO

PSINet

schoff@psi.com

Current Internets Provide

- **Universal IP for dialup PC's to T3 connected ServerFarms,**
- **An enormously complex world wide topology,**
- **A platform that supports the old Internet application models (such as client server, unicast),**
- **Textual applications and limited graphical applications (Web) support.**

Current Internets Don't Provide

- **Bandwidth Commitments**
- **Latency Guarantees**
- **Prioritization**
- **Security**

- **The current operation is more like US Postal Service First Class Mail**
 - when it works it is extremely cost effective
 - when it doesn't - there is frustration (minimally)

What Is Needed Today

- Latest Internet Applications need an additional operational model for the current Internet
- The Real-Time Internet Needs to Support Rich Media:
 - Audio
 - Video
 - 3D Graphics, etc.
- It needs to support newer corporate applications:
 - real-time document conferencing, etc
- It needs to support gaming
- PSINet can support these needs today.

■ **Think of FEDEX as a metaphor**

■ **Minimally:**

- **Guaranteed Delivery**
- **Prioritized Delivery**
- **Delivered by a certain time**

**The Real Time Internet Becomes Interactivity
Platform for all corporate and consumer
applications**

Bandwidth == Rich Media

Low Latency == Interactive Media

TCP/IP+ == Uniform Programming Platform

Internet == Leveraged Distribution Mechanism

■ Centralized Resources and Proprietary Architectures

- terminal to mainframe architecture
- centralized communications
- proprietary protocols

■ High Latency Networks

- whether X.25 or “Router Only” networks
- are poor for interactive applications

■ Caching Won't Work

- while it somewhat works for the current Web
- interactive voice, audio, gaming, etc. are not suited well for caching since the information is highly variable

Applications

What we really use.

IP

Where the routers are - Universal Programming

ATM/FR

Where we guarantee interactivity.

- We layer IP Routers over ATM/FR Switches in the worldwide Internet
- We Configure Specific Servers and Routers to take advantage of it
- Then we guarantee: latency, priority, bandwidth to the current installed base and current application models

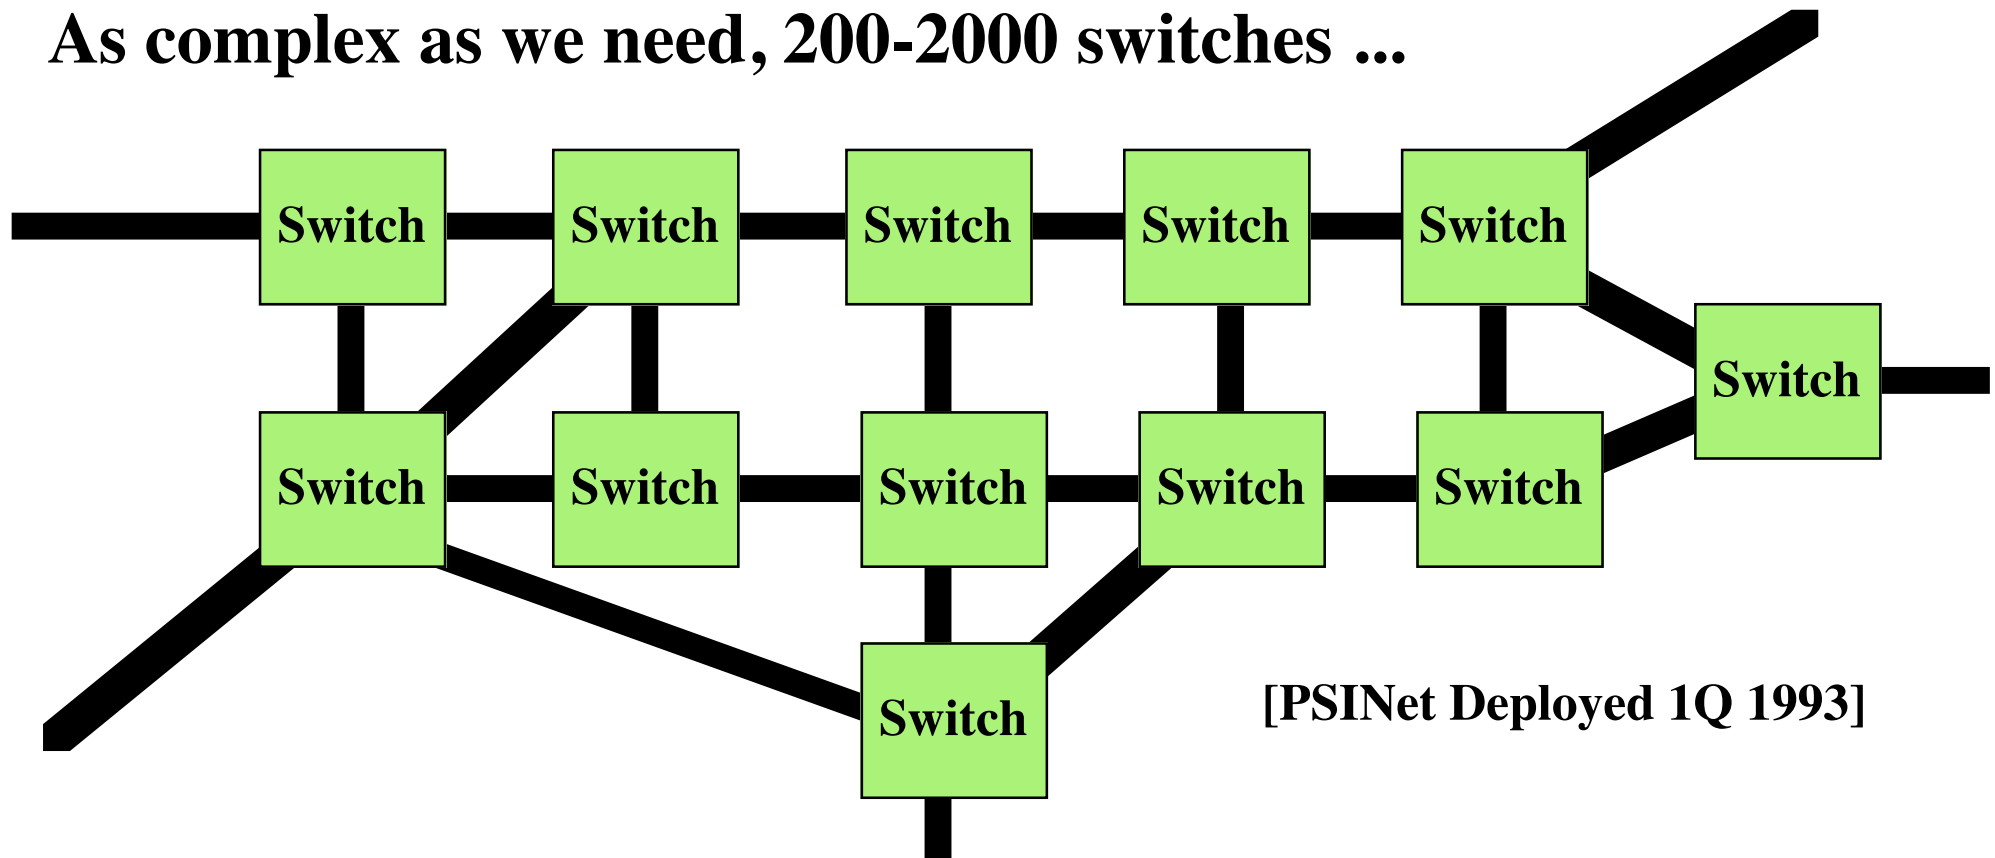

- **PSINet Technology allows virtual Internets to be created within the PSINet switching fabric.**
- **Not only applications can be managed and prioritized but so can the virtual Internets.**
- **Advances in network management and delivery on any virtual Internet benefits all virtual networks within PSINet.**
- **Customers may participate in one or more Internets.**

We Build the ATM/FR Fabric

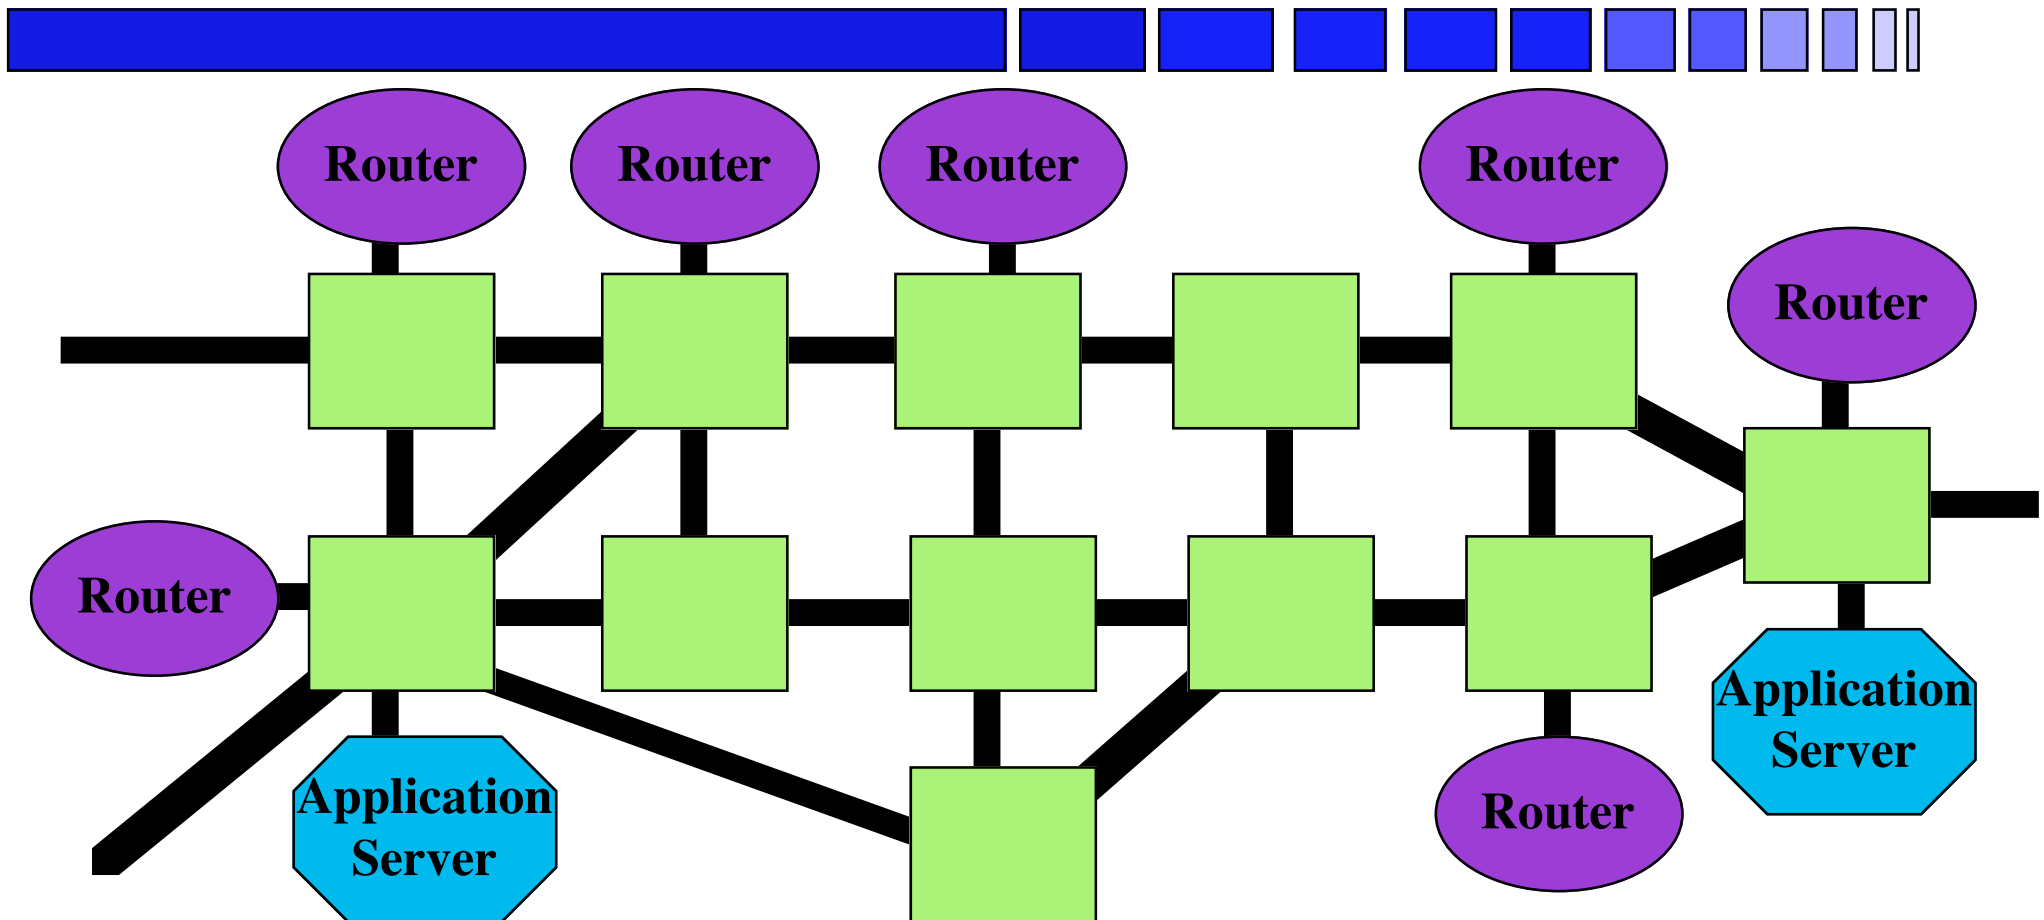

As complex as we need, 200-2000 switches ...

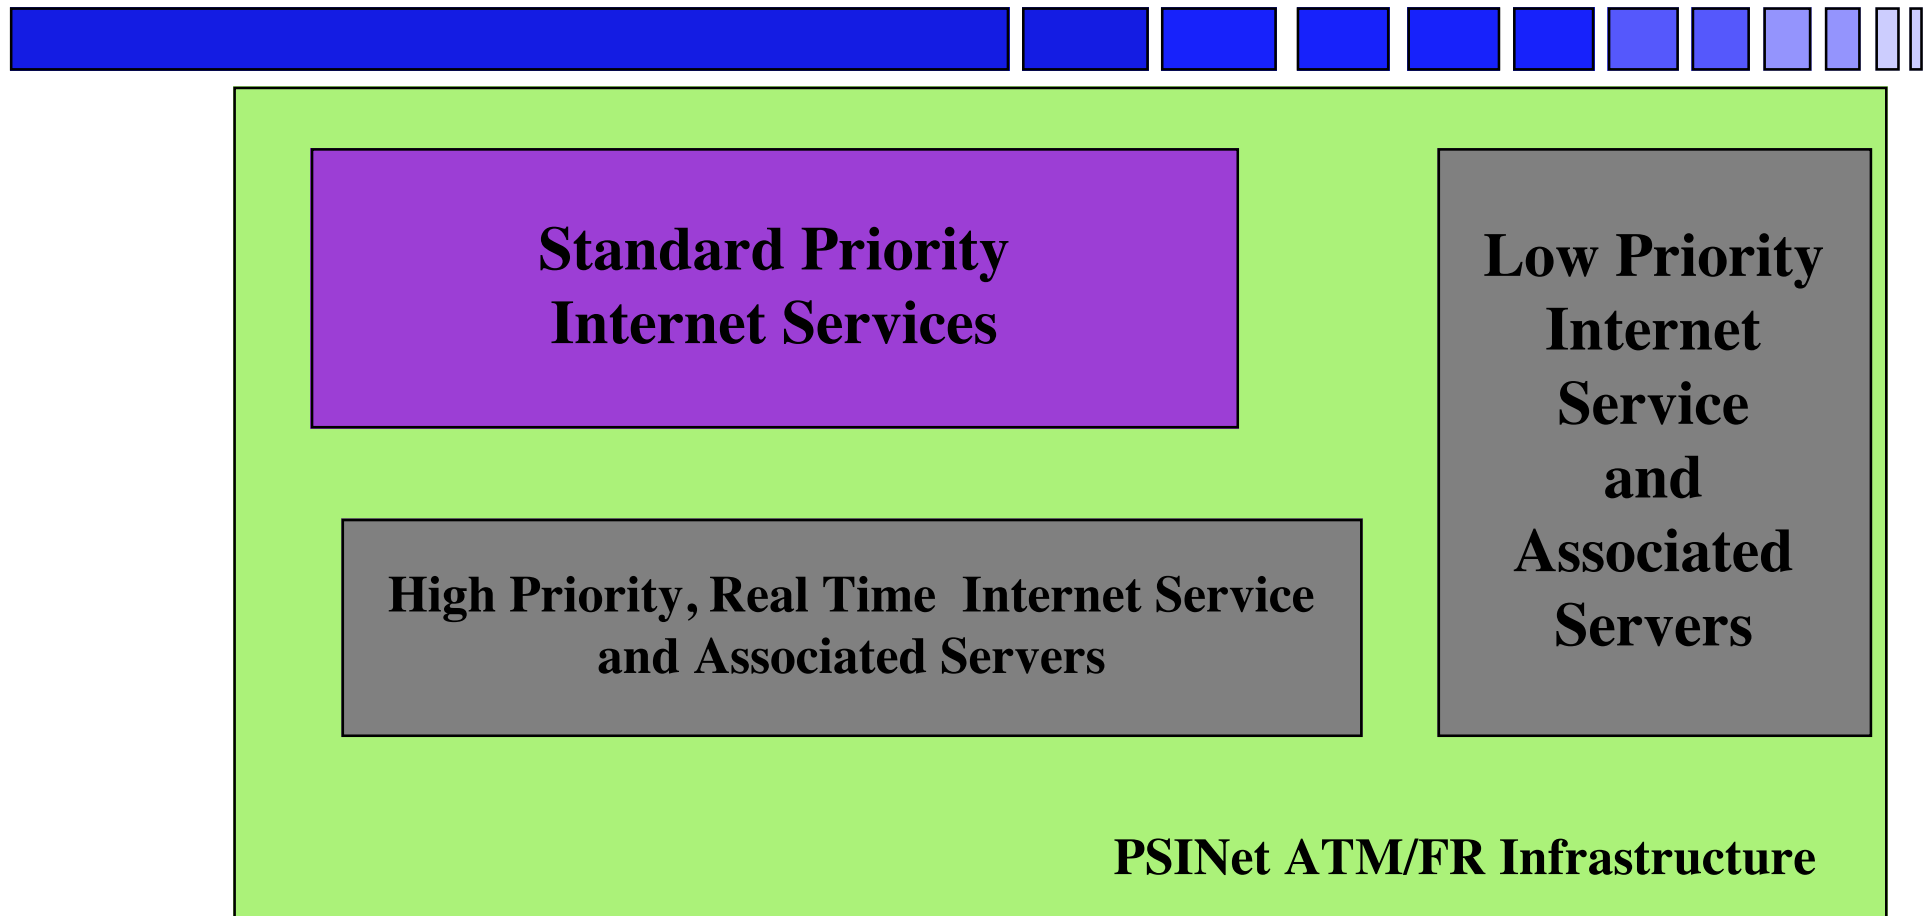

[PSINet Deployed 1Q 1993]

Which Exclusively move the Bits - Faster than Routers. Page - 10

Add the Routers and Servers

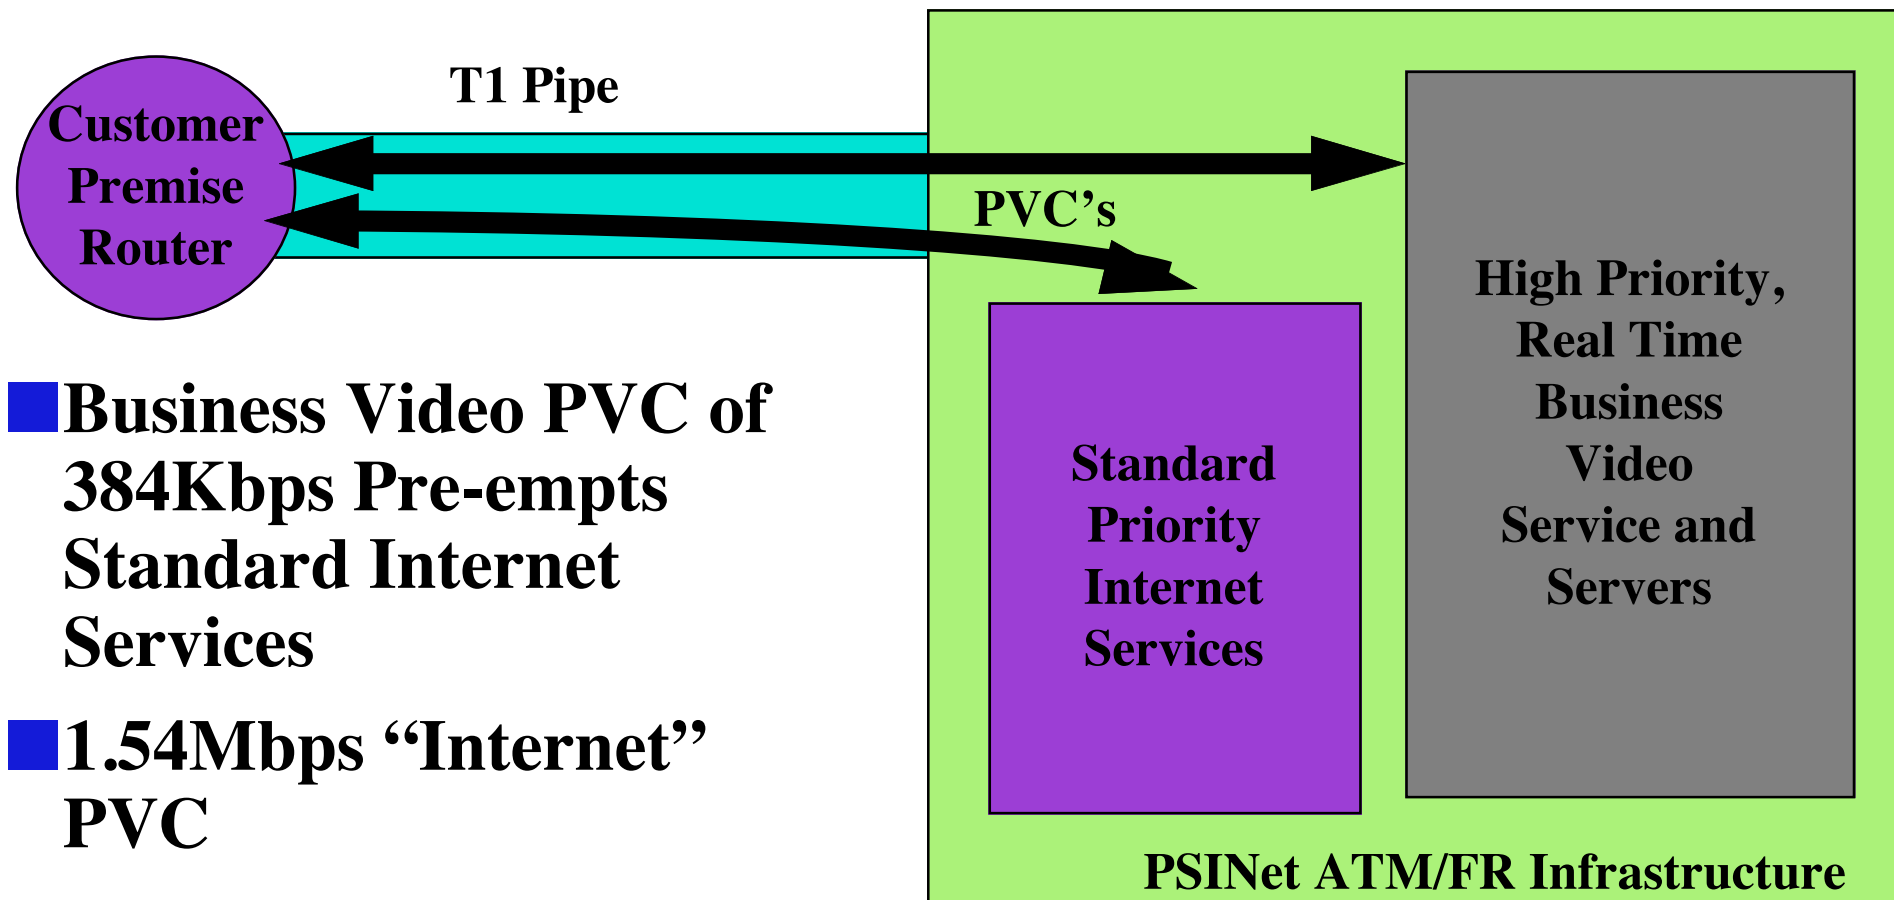

**So we Can Now Provide Different Types of IP Service,
and IP topologies to support them**

The key for lower or higher prioritization: Servers must be inside the network and distributed

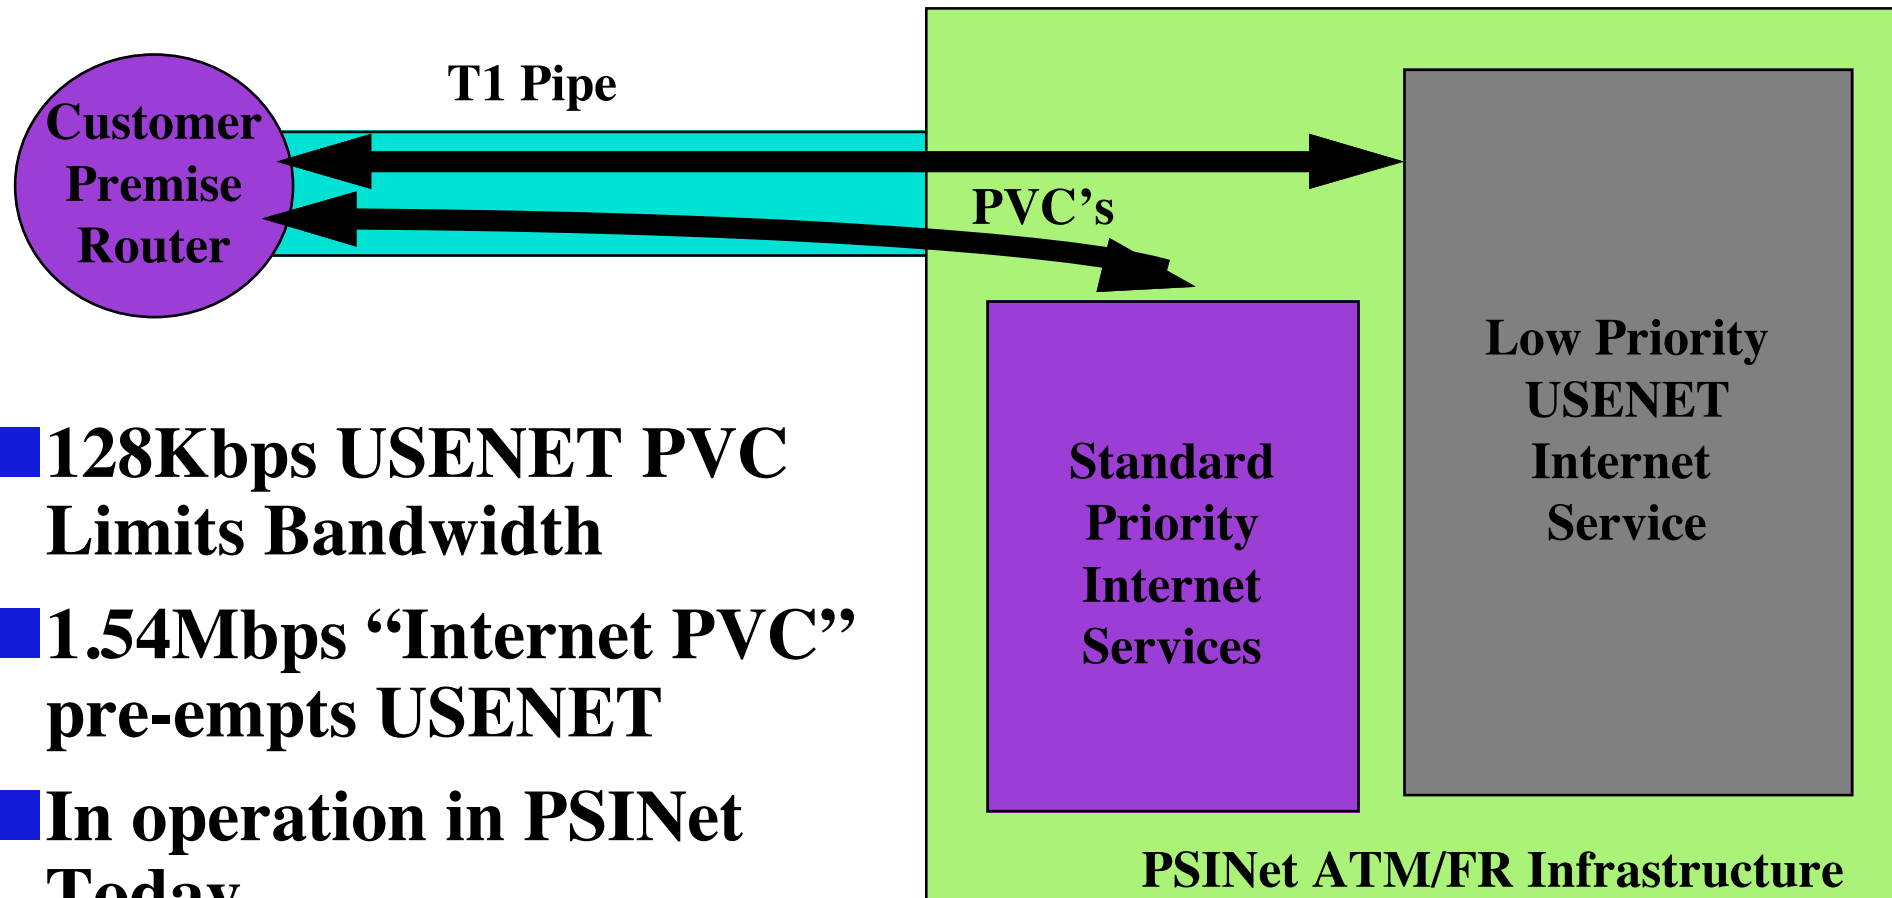

High Priority Application Example: Business Video

■ **Business Video PVC of 384Kbps Pre-empt's Standard Internet Services**

■ **1.54Mbps "Internet" PVC**

Low Priority Application Example: USENET

- **128Kbps USENET PVC Limits Bandwidth**
- **1.54Mbps “Internet PVC” pre-empts USENET**
- **In operation in PSINet Today**

■ **Currently there is quite a bit of informal “entertainment”:**

- MOO’s
- MUD’s
- Bridge
- some uses of CUSEEME and MBONE
- XTREK, etc
- a few LAN Based Consumer Games running over IP
- obviously “surfing the web”
- chat

■ **The Next Phase is Formal Real-Time Entertainment, where many people spend real money**

■ **Gaming on the Internet will be a 1996 Formal Reality**

■ **Driven by Home PC's with Modems (conservatively):**

- June 95: 33M, 10M w/Windows and w/Modems
- June 95: 1/3 of on-line users play games
- 1998: 57M, 32M w/Windows, w/Modems
- 1998: 54% of computers w/Modems have Internet Access

■ **so in 1998**

- if average gamer plays 2 hours/month
- and pays average of \$2/hour
- market size is \$600M/year

- **real-time/low-latency**
- **3D**
- **Titles Found in the Computer stores, not custom network titles**
- **multi-player**
- **real-time distribution of players' voices**
- **where:**
 - at home
 - at work
 - at the Mall

Gaming - The Killer Application

“Entertainment is the 3000 pound gorilla in America’s living room. Information although important to many, takes a back seat. This reality comes through in all of Odyssey’s Research”

**Nicholas Donatiello, Jr.
President & CEO, Odyssey**

- **PSINet is now tuned to real-time multi-media, multi-player interactive gaming**
- **Server's are now in place for Gaming partner's to use**
- **Guaranteed low latency is a reality**
- **technology for gaming is usable for other business purposes**

- **Superior Internet Technology is needed to provide Real Time Internets for business and entertainment.**
- **Demand for Internet entertainment is on the rise and will materialize in 1996 in the form of interactive multi-player gaming.**
- **All Internet uses benefit from superior technology and experience.**
- **PSINet is uniquely engineered and positioned to provide real time Internet services today.**

- **Strategic Partnership with MPATH Interactive and its network publishing platform for games and its title partners**
- **Partnership with Microprose for the Civilization game**
- **Strategic Partnership with Borta Inc. for its games and technology**
- **Partnership with Vocaltec for its “Internet Phone” software for Windows**

■ **Phone: 1-703-904-4100**

■ **Email: info@psi.com**

■ **Web: http://www.psi.net**

■ **Nasdaq: PSIX**

Interleaf

What We Have Now

- **Company “storefronts” / some advertising**
- **Internal memos / reports**
- **“Lightweight” academic material**
- **Experimentation with commercial transactions**
- **Several optometrists**

Interleaf

What's In Demand

- **More serious in-house and external corporate publishing**
- **Internal corporate information access / distribution**
- **Material for serious academic and business research**
- **Book / magazine publishers**

Interleaf

Business Is A Big Part of The Vision

“With the hyperlink kind of paradigm that you see on the Web, you can imagine putting all of your corporate documentation on there ... even design files for machines.”

Bill Joy of Sun Microsystems
Information Week, July 17, 1995

Interleaf

What's The Attraction?

- **Online distribution of simple information**
- **Reasonably nice format**
- **Ability to browse with hyperlinking between documents**
- **Open access to all Web users and all Web software**

What Needs Can Be Anticipated?

- **Central repository to drive multiple output formats and support collaborative authoring / editing**
- **Data format capable of protecting investment in complex, long-lived data**
- **Data reuse**
- **Linkages to other databases and business systems**

My Observations

- Wild enthusiasm for the Web
- Desire for simplicity
- In reality, a wide range of needs / requirements

Interleaf

Potentially Huge Trade-off

*Desire for
Simplicity*

*Wide Range
of Needs*

Interleaf

Common Questions

“What’s the difference between SGML and HTML?”

“If you have HTML, is there any need for SGML?”

Interleaf

A Closer Look at SGML

- ISO standard since 1986
- Focus on structure and content, no proprietary formatting codes
- Open interchange / platform independence
- The standard chosen for HTML

Interleaf

In a Defined Structure (DTD)

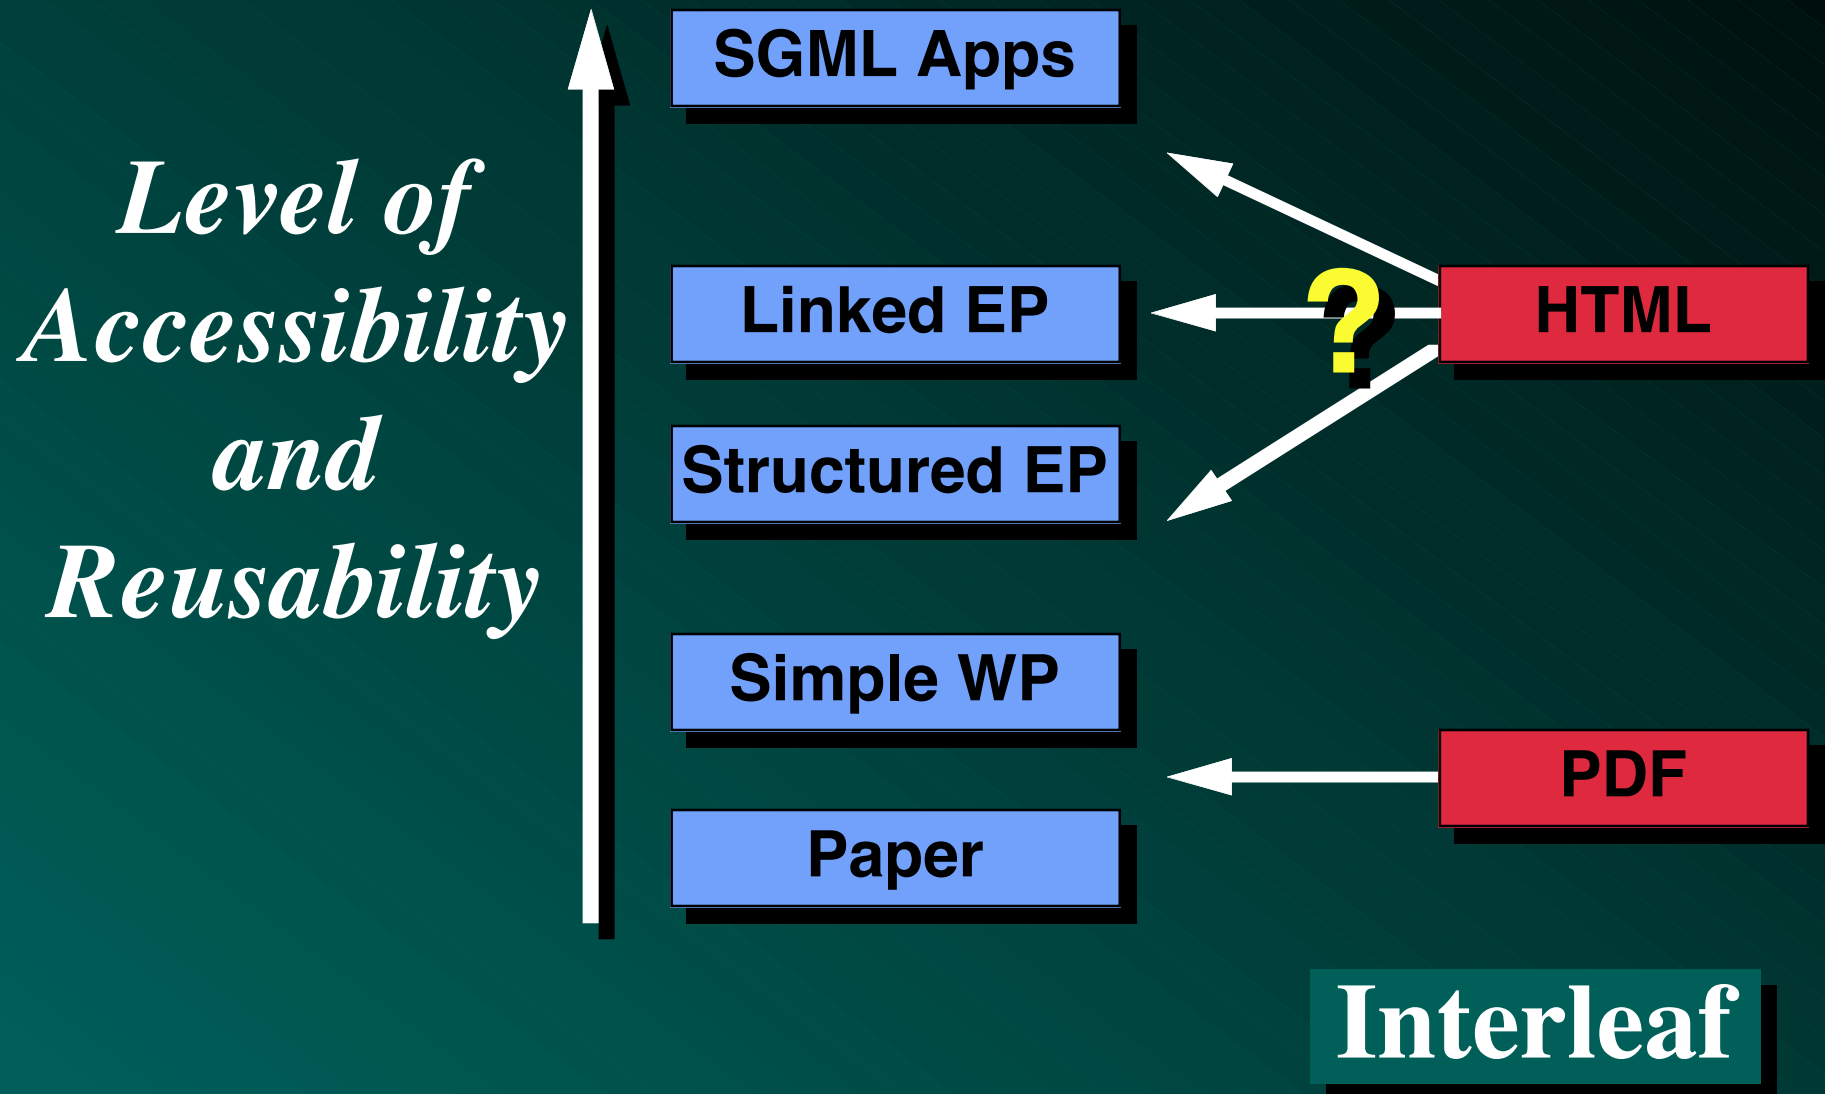

Each DTD Is An “Application”

... Including HTML

HTML In The Food Chain

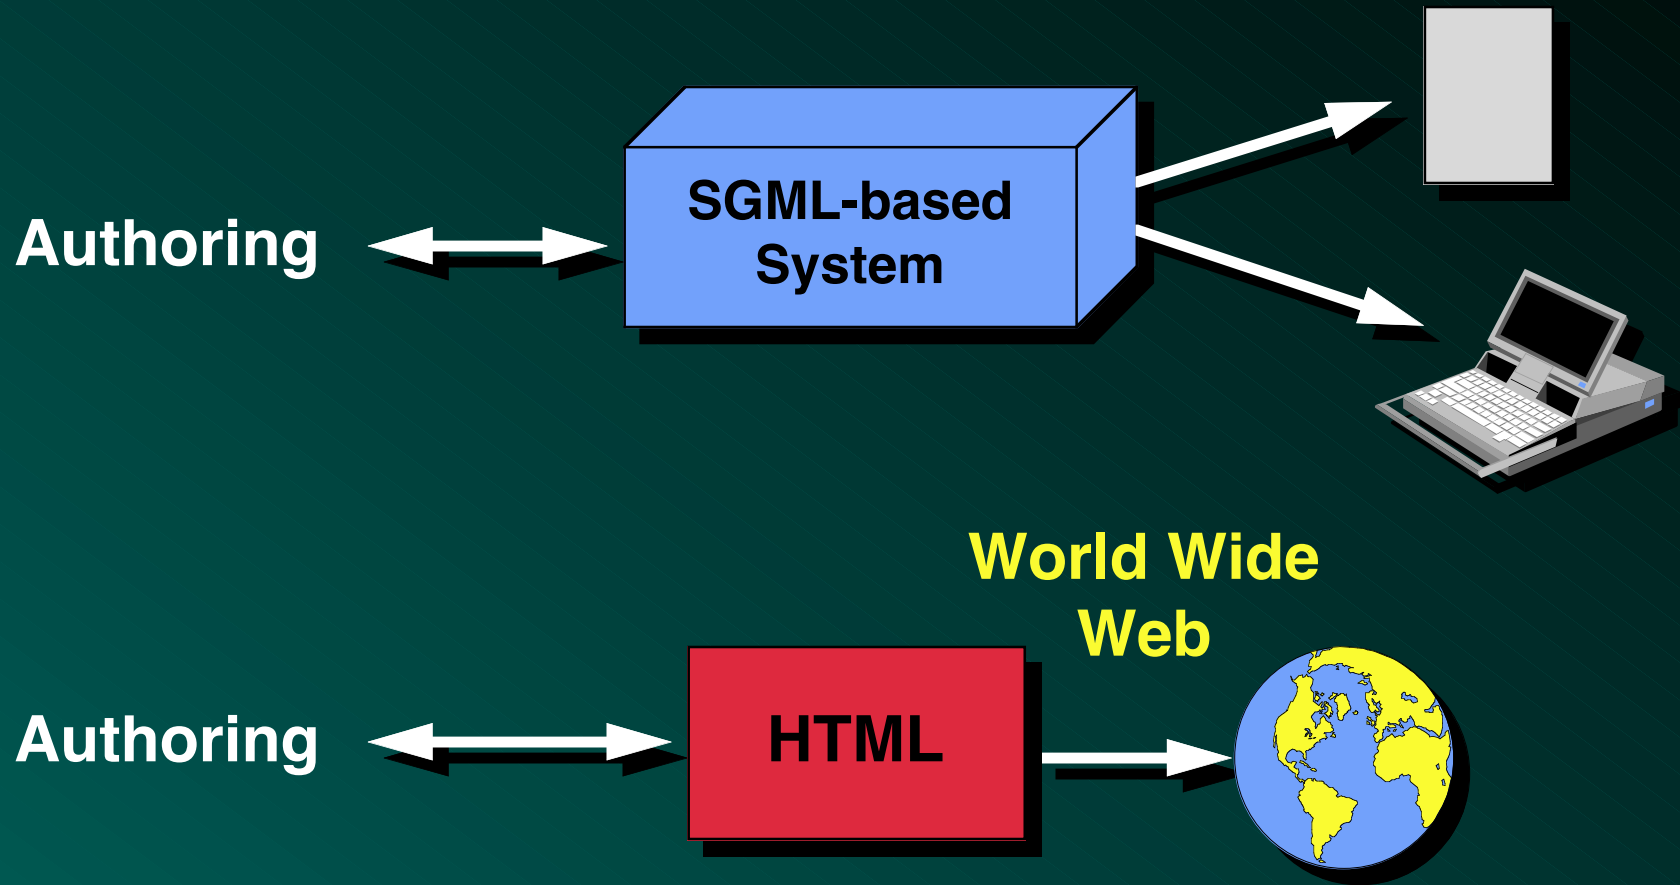

More Questions ...

“Is HTML a general interchange format?”

“Could HTML be the form in which I store my documents?”

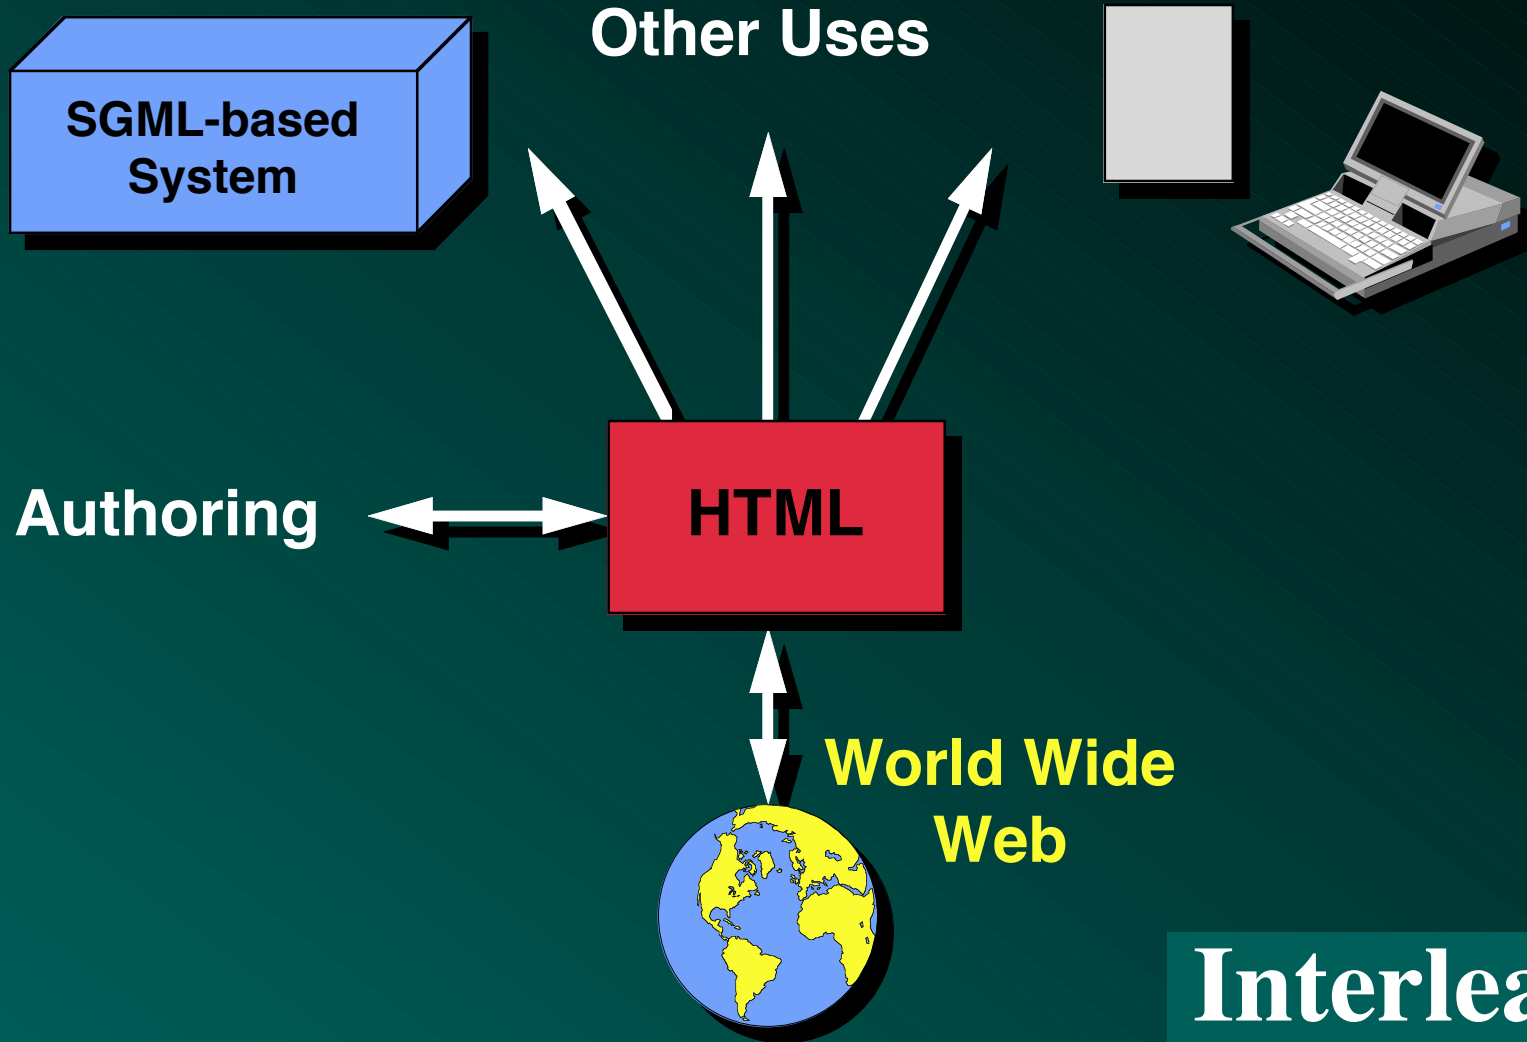

Interleaf

How To Put Them Together?

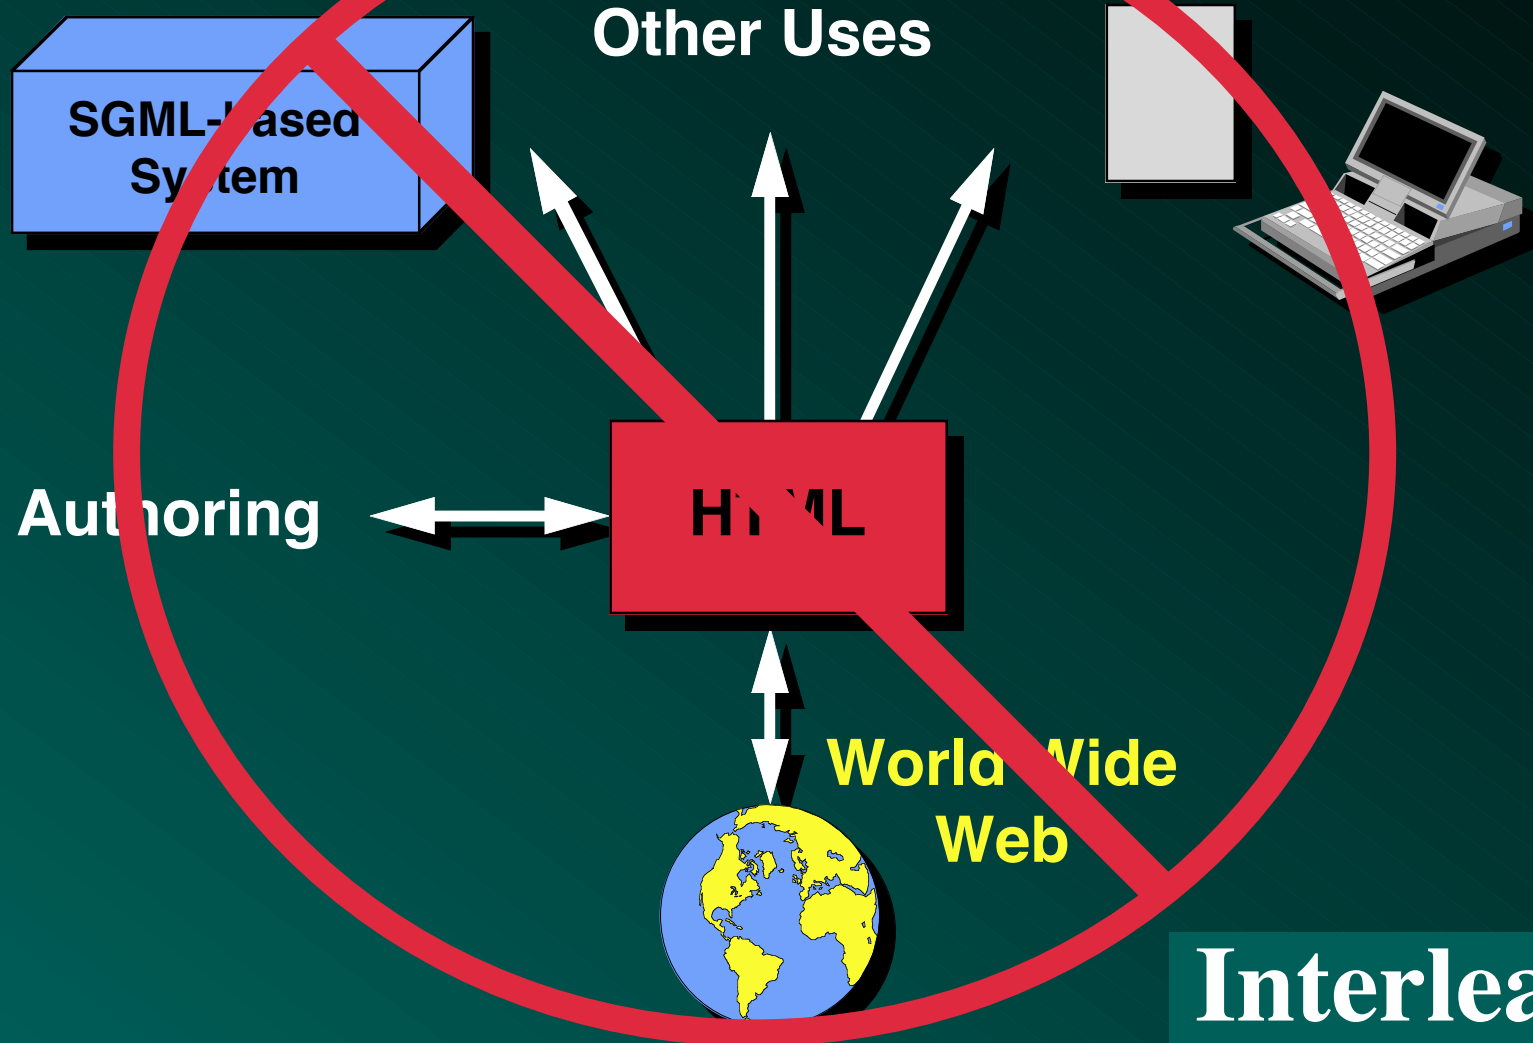

Interleaf

HTML In The Center?

HTML In The Center?

Interleaf

Why Not?

- **Because HTML is a lowest common denominator, “one size fits all” solution**
- **Because HTML itself is rapidly evolving**
- **To avoid the up-translation problem**

The Up-Translation Problem

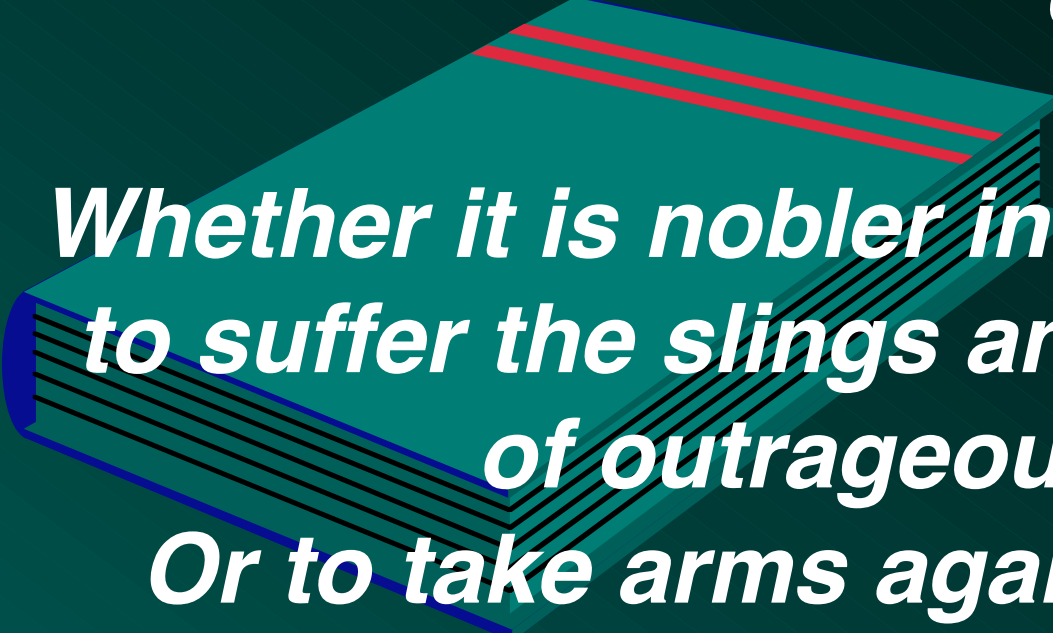

“To be or not to be, that is the question:

Interleaf

The Up-Translation Problem

“To be or not to be, that is the question:

*Whether it is nobler in the mind
to suffer the slings and arrows
of outrageous fortune
Or to take arms against a sea
of troubles and by opposing...”*

Interleaf

The Up-Translation Problem

Simpler Form:

Interleaf

The Up-Translation Problem

Simpler Form:

“Is this jive worth it?”

Interleaf

The Up-Translation Problem

“Is this jive worth it?”

Interleaf

The Up-Translation Problem

“Is this jive worth it?”

Interleaf

The Up-Translation Problem

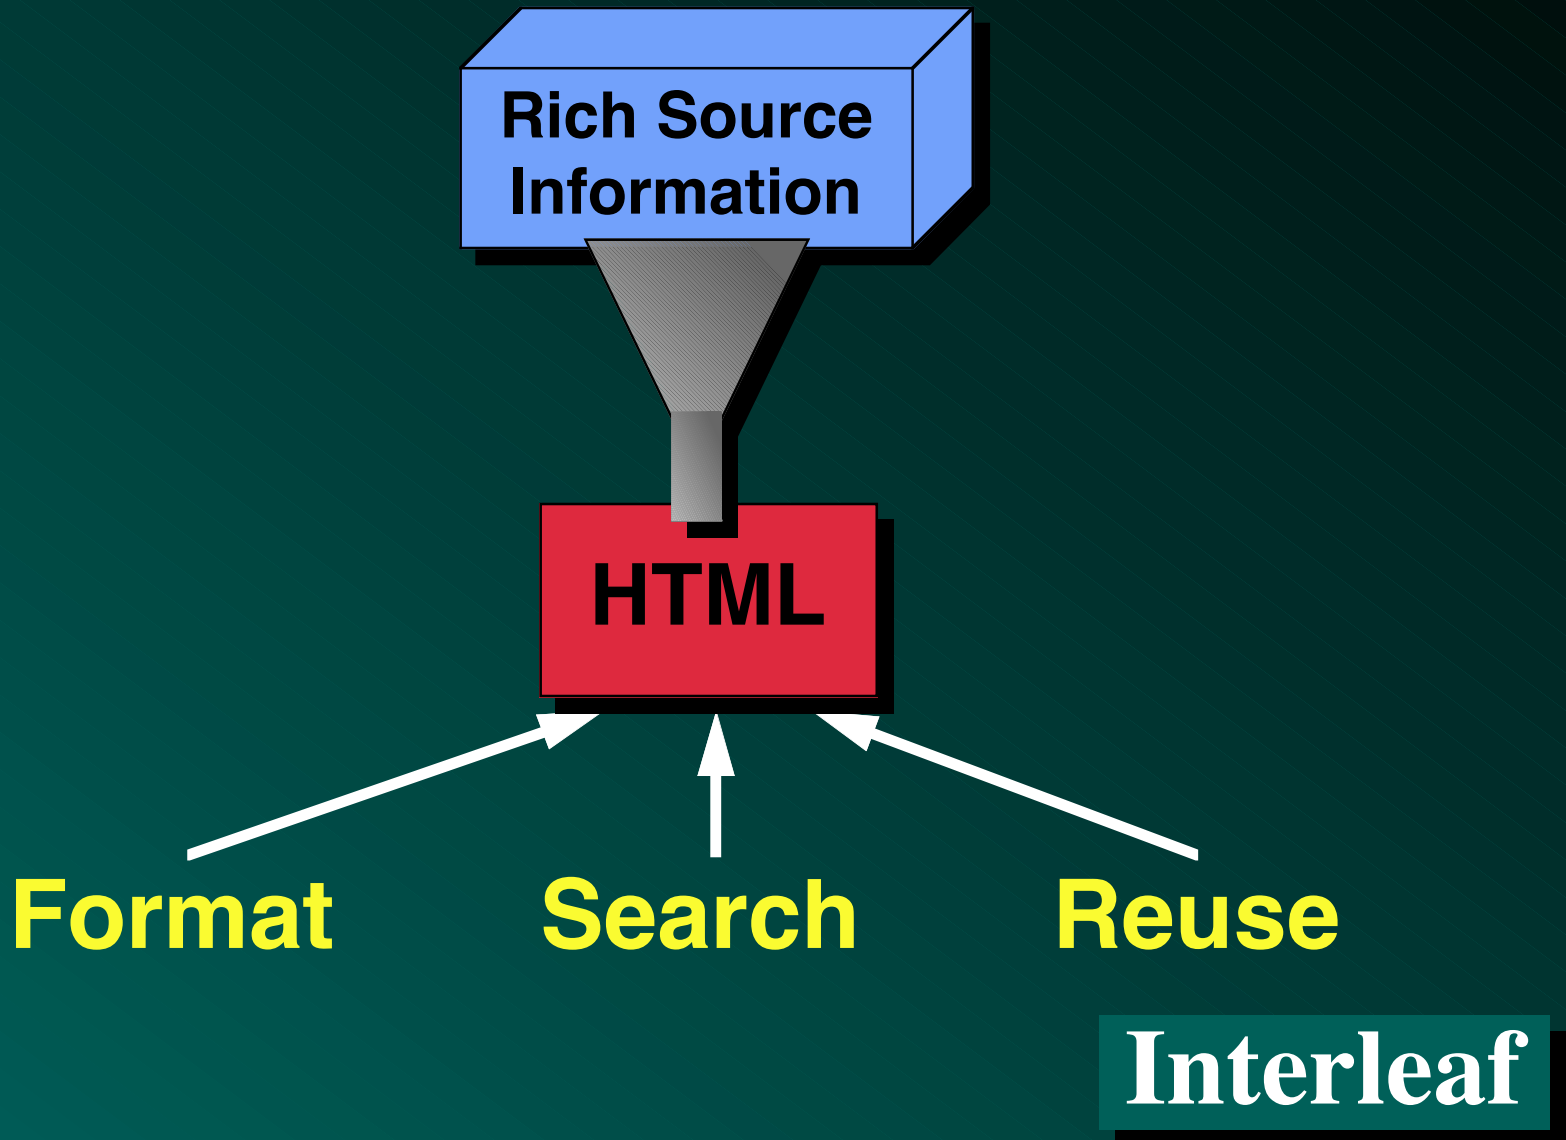

*“To be or not to be, that is the question:
Whether it is nobler in the mind
to suffer the slings and arrows...”*

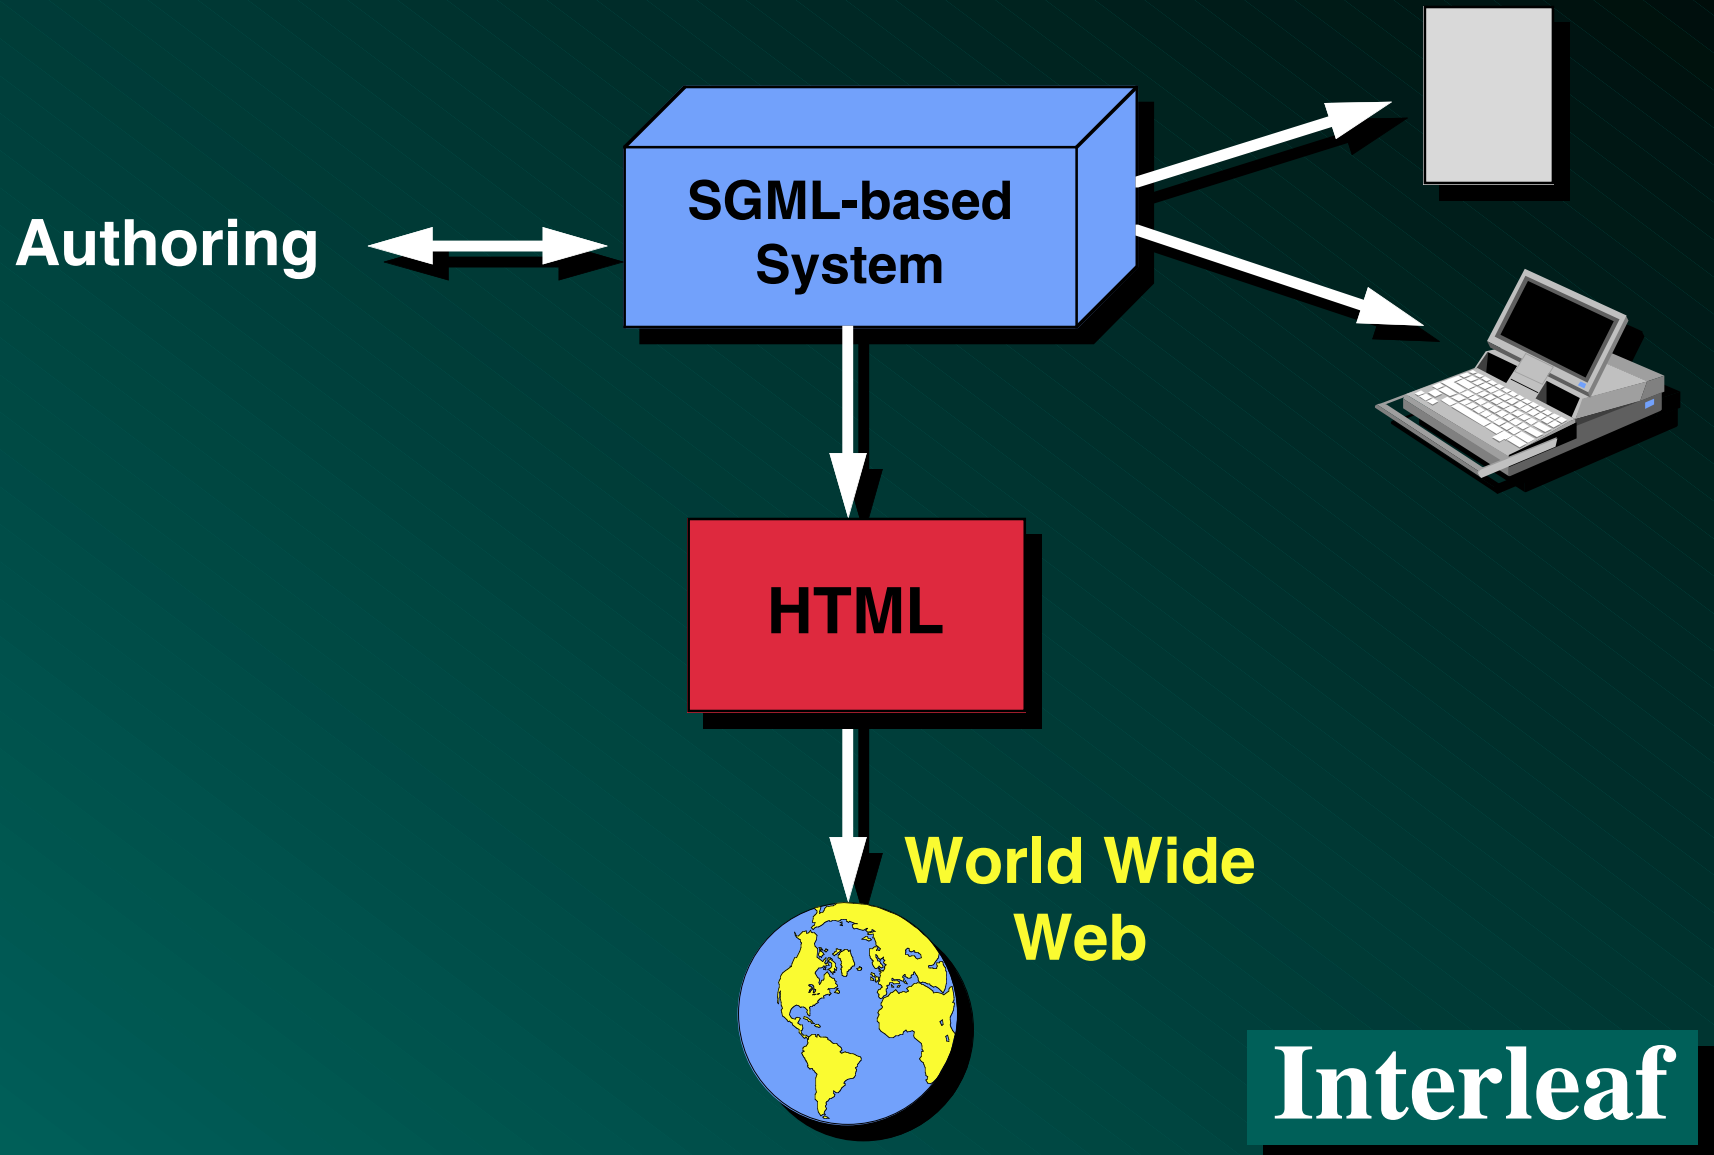

“Is this jive worth it?”

Interleaf

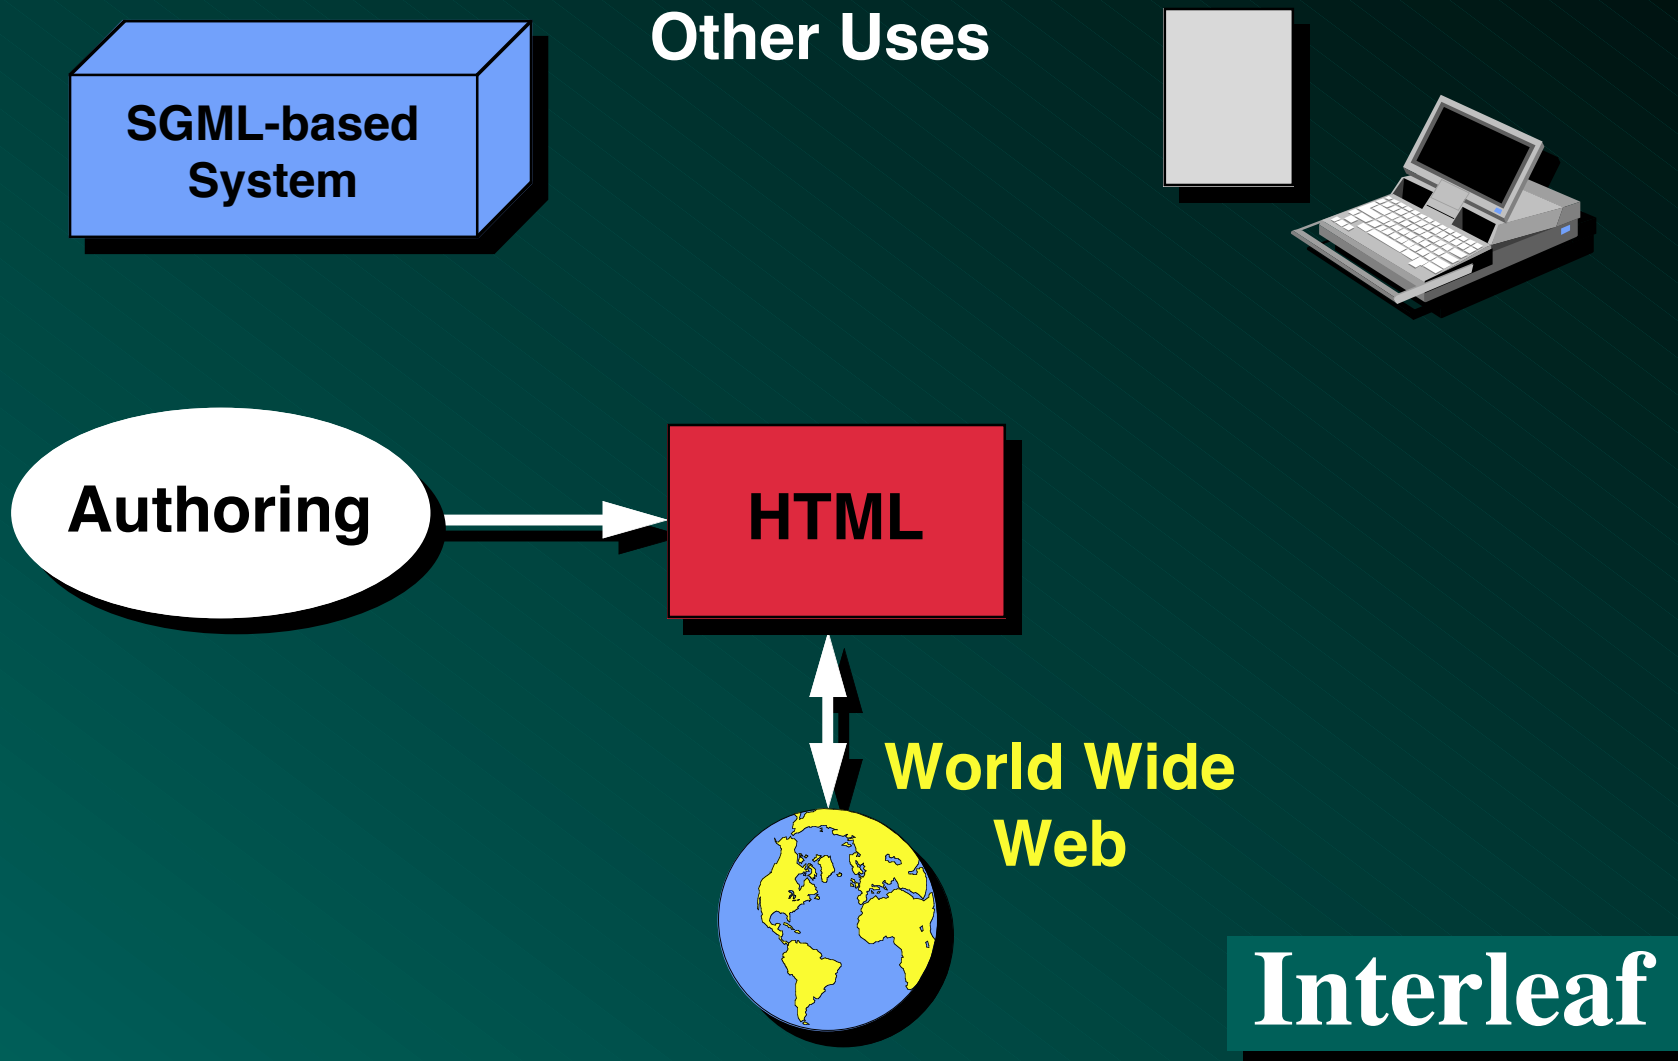

HTML Has The Same Issue

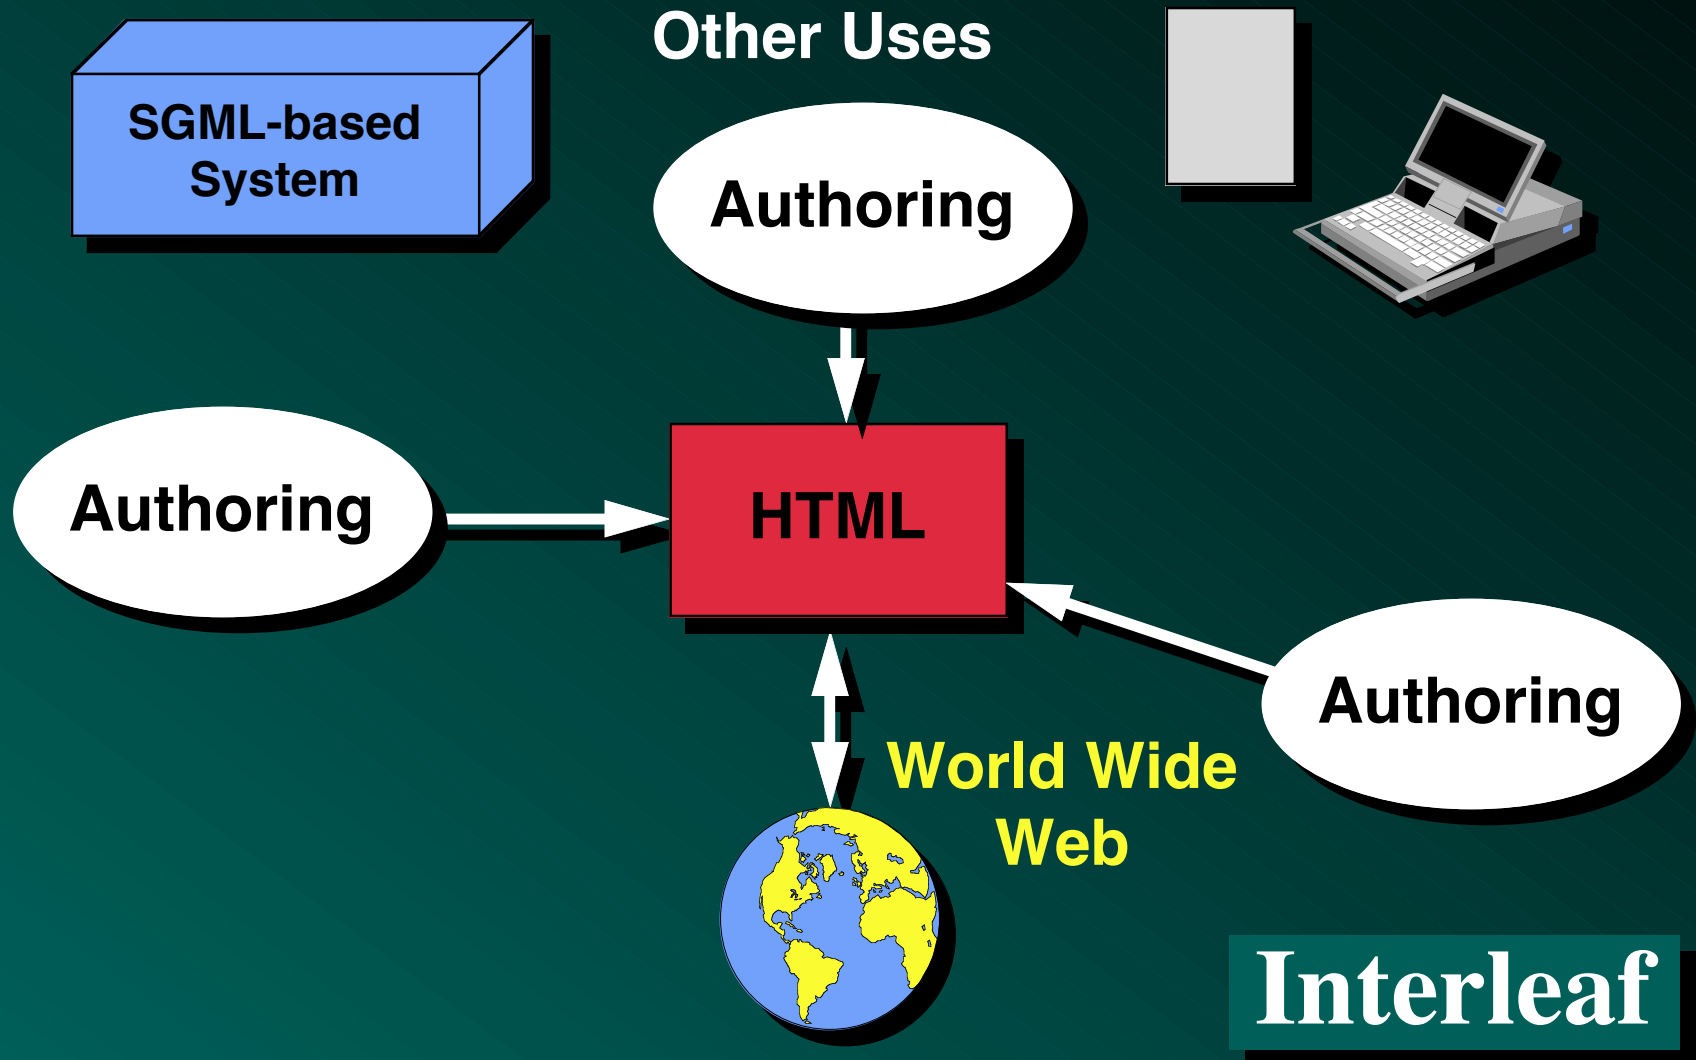

HTML As A Publishing Medium

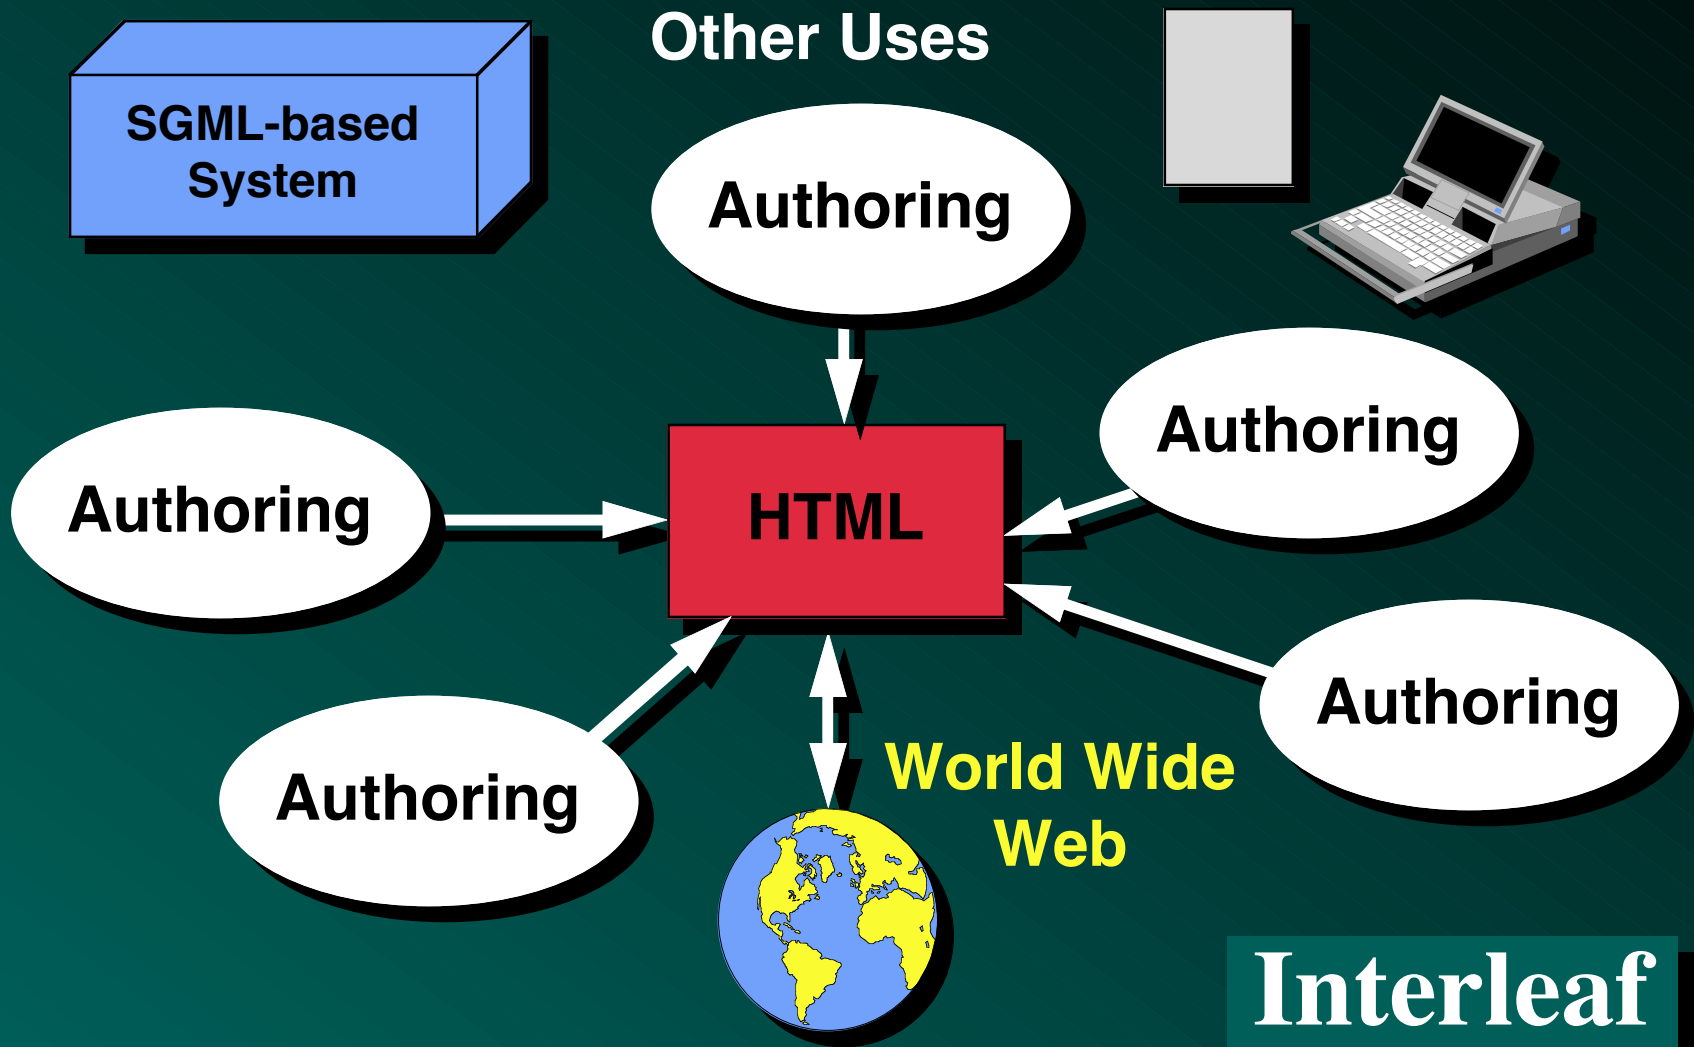

HTML In The Center?

HTML In The Center?

HTML In The Center?

Same Principle At Any Scale

Interleaf

Different Approaches ...

*Desire for
Simplicity*

*Wide Range
of Needs*

Interleaf

HTML Addresses Simplicity

- **Simple and forgiving**
- **Focus on connectivity**
- **Standard, predefined set of Web objects**

SGML Addresses The Wide Range

- **Powerful information access and reuse**
- **Focus on structure and content, plus linking**
- **Flexible, application-specific objects**

Interleaf

What's Wrong With Simplicity?

Interleaf

Many Objects vs. One Object

Interleaf

...Not A Quantum Leap!

... Nor A Lack of Open Access

Summary

- **HTML is an SGML application**
- **Not in competition with SGML**
- **HTML is meant for electronic distribution over the Web**
- **Not for archiving data in a repository**

HTML Scalability

- But HTML can take advantage of SGML's power
- And still provide a simple backbone structure
- It is possible to build a scalable HTML / SGML web, full of power without sacrificing simplicity

Thank you, merci, danke, arigato!

SGML/HTML Tutorial

Diane Sandstrum

Regional Training Manager

Interleaf, Inc.

Agenda

- SGML Basics
- How HTML fits into SGML
 - what features are/aren't utilized
- How HTML can evolve with SGML

Goals

- To read basic components of DTD's
 - specifically the HTML DTD
- Link Eric's ideas to more concrete technical examples

First, back to what Eric said...

SGML Is About Objects

DTD

~~FORMATTING?~~

So what is a DTD?

- Document Type Definition (DTD)
- Provides a logical analysis of document structure, written in a known grammar
 - Identifies document elements
 - Establishes the relationship of document elements to each other
 - “Title is followed by subtitle, author, para . . .”

So what does a DTD look like?

So what does a DTD look like?

```
<!-- The following is a sample DTD. -->
<!ENTITY % paras      "(PARA|LIST)">
<!ENTITY % content     "EMPHASIS|#PCDATA">

<!ELEMENT  DOC      - - (CHPT+)                >
<!ELEMENT  CHPT     - - (TITLE, (SECT+))        >
<!ATTLIST  CHPT      label CDATA #IMPLIED>
<!ELEMENT  TITLE    - - ((%content;)+)          >
<!ELEMENT  SECT     - - (TITLE?,
                        ((%paras;)+, SSECT*)+)>
<!ATTLIST  SECT      label CDATA #IMPLIED>
<!ELEMENT  SSECT    - - (TITLE, (%paratxt;)+)>
<!ATTLIST  SSECT     label CDATA #IMPLIED>
```

And SGML markup?

```
<DOC>
<CHPT LABEL='1'><TITLE>Overview</TITLE>
<SECT><TITLE>A closer look at SGML and
HTML</TITLE>
<PARA>We'll examine SGML basics, then see
how SGML and HTML fit together.</PARA>
<PARA>Then we'll discuss how SGML and
HTML could evolve together.</PARA>
</SECT>
</CHPT>
</DOC>
```

And HTML markup?

```
<HTML>
<HEAD><TITLE>Overview</TITLE></HEAD>
<BODY><H1>A closer look at SGML and
HTML</H1>
<P>We'll examine SGML basics, then see
how SGML and HTML fit together.</P>
<P>Then we'll discuss how SGML and
HTML could evolve together.</P>
</BODY>
</HTML>
```

Same basic markup, but different tags are used

Main DTD components

- Elements
- Attributes
- Entities

Sample DTD

```
<!-- The following is a sample DTD. -->  
<!ENTITY % paras      "(PARA|LIST)">  
<!ENTITY % content     "EMPHASIS|#PCDATA">
```

```
<!ELEMENT  DOC      - - (CHPT+)                >  
<!ELEMENT  CHPT     - - (TITLE, (SECT+))        >  
<!ATTLIST  CHPT      label CDATA #IMPLIED>  
<!ELEMENT  TITLE    - - ((%content;)+)         >  
<!ELEMENT  SECT     - - (TITLE?,  
                        ((%paras;)+, SSECT*))+>  
<!ATTLIST  SECT      label CDATA #IMPLIED>  
<!ELEMENT  SSECT    - - (TITLE, (%paratxt;)+)>  
<!ATTLIST  SSECT     label CDATA #IMPLIED>
```

Sample DTD

```
<!-- The following is a sample DTD. -->
<!ENTITY % paras      "(PARA|LIST)">
<!ENTITY % content     "EMPHASIS|#PCDATA">

<!ELEMENT  DOC      - - (CHPT+)                >
<!ELEMENT  CHPT     - - (TITLE, (SECT+))        >
<!!ATTLIST CHPT      label CDATA #IMPLIED>
<!ELEMENT  TITLE    - - ((%content;)+)          >
<!ELEMENT  SECT     - - (TITLE?,
                        (%paras;)+, SSECT* )+ )>
<!!ATTLIST SECT      label CDATA #IMPLIED>
<!ELEMENT  SSECT    - - (TITLE, (%paratxt;)+)>
<!!ATTLIST SSECT     label CDATA #IMPLIED>
```

Sample DTD

```
<!-- The following is a sample DTD. -->
```

```
<!ENTITY % paras      "(PARA|LIST)">
```

```
<!ENTITY % content     "EMPHASIS|#PCDATA">
```

```
<!ELEMENT  DOC      - - (CHPT+)                >
```

```
<!ELEMENT  CHPT     - - (TITLE, (SECT+))        >
```

```
<!ATTLIST  CHPT      label CDATA #IMPLIED>
```

```
<!ELEMENT  TITLE    - - ((%content;)+)         >
```

```
<!ELEMENT  SECT      - - (TITLE?,  
                           ((%paras;)+, SSECT* )+)>
```

```
<!ATTLIST  SECT      label CDATA #IMPLIED>
```

```
<!ELEMENT  SSECT    - - (TITLE, (%paratxt;)+)>
```

```
<!ATTLIST  SSECT     label CDATA #IMPLIED>
```

ELEMENTS

- Identify the specific pieces of the documents
- Contain data, other elements, or both

ELEMENTS - the markup

```
<chapter>
<title>Introduction to SGML</title>
<para>This gives you an overview of
how SGML is used.  The DTD defines
the <emph type='i'>structure</emph>
of the elements.</para>
</chapter>
```

BEGIN TAG

<chapter>

<title>

END TAG

</chapter>

</title>

ELEMENTS - the structure

```
<chapter>
<title>Introduction to SGML</title>
<para>This gives you an overview of
how SGML is used. The DTD defines
the <emph type='i'>structure</emph>
of the elements.</para>
</chapter>
```

- CHAPTER contains other elements (title, para).
- TITLE contains data characters.
- PARA contains data characters and an embedded emph element.

Element Declaration

- Defines an element and its content
- Describes how many times and when elements occur
- SGML Syntax:

```
<!ELEMENT name content_model>
```

Content Model

- Defines the content of an element

OTHER ELEMENTS:

```
<!ELEMENT chapter (title, para)>
```

DATA:

```
<!ELEMENT title (#PCDATA)>
```

DATA AND OTHER ELEMENTS:

```
<!ELEMENT para (#PCDATA | EMPH) *>
```

The DTD

```
<!ELEMENT chapter (title, para)>
<!ELEMENT title   (#PCDATA)>
<!ELEMENT para    (#PCDATA|EMPH)*>

of the elements.</para>
</chapter>
```

Structure and Order

- Defined in the content model
 - Special notations used
- Can specify:
 - Required?
 - Number of times
 - Order of elements

SGML Notation

- Ordering indicators:
 - , All must occur in the order entered
 - | Select one of alternatives
 - & All must occur in any order

```
<!ELEMENT letter (opening,body,closing)>
```

```
<!ELEMENT list (bullitems | numitems)>
```

```
<!ELEMENT memo (to & from & date),body)>
```

SGML Notation

- Occurance indicators:

- ? Optional (0 or 1 times)

- * Optional and repeatable (0 or more)

- + Required and repeatable (1 or more)

```
<!ELEMENT manual (title,chapter+,index?)>
```

```
<!ELEMENT para (title?,para,  
                (subpara,subpara+)?)>
```

```
<!ELEMENT order (appetizer*,soup?,  
                entree,dessert+)>
```

Using SGML Elements

- **Variety**
 - Define what you need
 - More robust documents (now or reuse)
 - Search & retrieval
- **Structure**
 - Defined and validated

Many Objects vs. One Object

SGML

Title

Abstract

Intro

Preface

Note

Summary

Document Structure

- Element declarations allow us to define the rules of the hierarchical structure of our documents

Structure Validation

- All SGML documents must be verified (parsed)
- Some information is **REQUIRED**
 - Can cause costly mistakes or serious errors if information is left out
- Maintains document integrity

The importance of verified structure ...

Those **WARNING** statements never made it into the print... I told you those were **REQUIRED!!**

Value of SGML elements:

- Focused search and retrieval
- Component level management
- Validated structure
- Flexible reuse
- Rich, robust documents

Attributes

ATTRIBUTES - the markup

```
<chapter id='ch1'>
<title>Introduction to SGML</title>
<para>This gives you an overview of
how SGML is used. The DTD defines
the <emph type='i'>structure</emph>
of the elements.</para>
</chapter>
```

Attributes

- Convey a characteristic, quality or condition of an element
- Store other (abstract) information that will travel with the doc
- SGML Syntax:

```
<!ATTLIST el_name attr_name values>
```

ATTRIBUTES - the DTD

```
<!ELEMENT chapter (title, para)>
```

```
<!ATTLIST chapter id CDATA>
```

```
<!ELEMENT emph      (#PCDATA)>
```

```
<!ATTLIST emph      type (b|i|u)>
```

Attribute usage - general

GENERIC FORMATTING:

```
<emph type='italic'>
```

DIMENSIONS:

```
<pict height='4.5in' width='3in'>
```

EXTERNAL FILE REFERENCES:

```
<graphic file="c:\pics\grph1.wmf">
```

Attribute usage - abstract

STATUS:

```
<report status='draft'>  
<para security='classified'>  
<sect user_level='advanced'>
```

CROSS-REFERENCES USING UNIQUE IDs:

```
<ref refid='tbl5'> <tbl id='tbl5'>
```

Value of attributes

- Allows more “abstract” information to be stored with your documents
- Focused search & retrieval
- Later formatting or reuse can be dependant upon these attributes

Entities

- Defined unit used to represent something else:
 - special characters
 - string of characters
 - external file reference
- Used in the DTD and in the markup

```
<!ENTITY name "what it represents">
```

Entity

DEFINED IN THE DTD:

```
<!ENTITY sgml "Standard Generalized  
Markup Language">
```

USED IN THE MARKUP:

```
<para>Many industries are adopting  
&sgml; to solve information  
management problems.</para>
```

Entity

DEFINED IN THE DTD:

```
<!ENTITY % paras "para|note|warn">
```

USED IN THE DTD:

```
<!ELEMENT section (title, %paras)>
```

Value of entities

- **Flexibility**

- Ease of replacing items globally
- Can manage entities separately, easier than updating files
- Build from a framework

- **Consistency**

- Always sure a phrase or item is represented properly

So what about HTML??

So what about HTML??

Let's take a look!

How HTML relates to SGML

- Examine HTML DTD
 - Elements/Structure
 - Attributes
 - Entities
- What features are utilized?

Let's Start at the Top...

```
<!ELEMENT HTML 0 0 (%html.content)>
```

```
<!ELEMENT HEAD 0 0 (%head.content)>
```

```
<!ELEMENT BODY 0 0 %body.content>
```

```
<!--===== ENTITIES =====-->
```

```
<!ENTITY % html.content "HEAD, BODY">
```

Continuing with the HTML DTD...

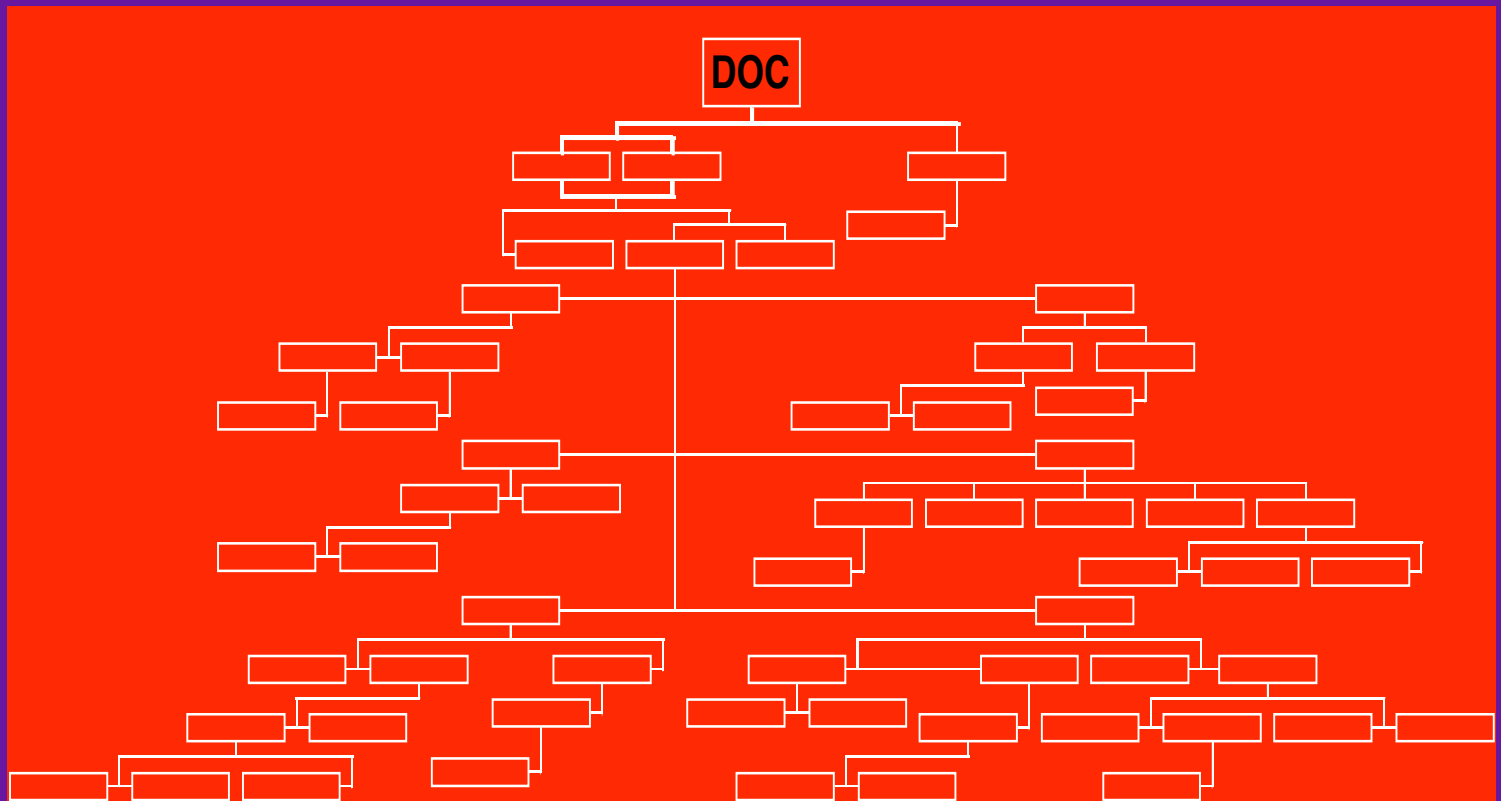

What HTML does do ...

- Cross-reference links
 - “Hot spots” in browsers
- External file references
 - graphics, etc.
- Entities
 - mainly used within the DTD
- Provides a backbone - a commonality between all users

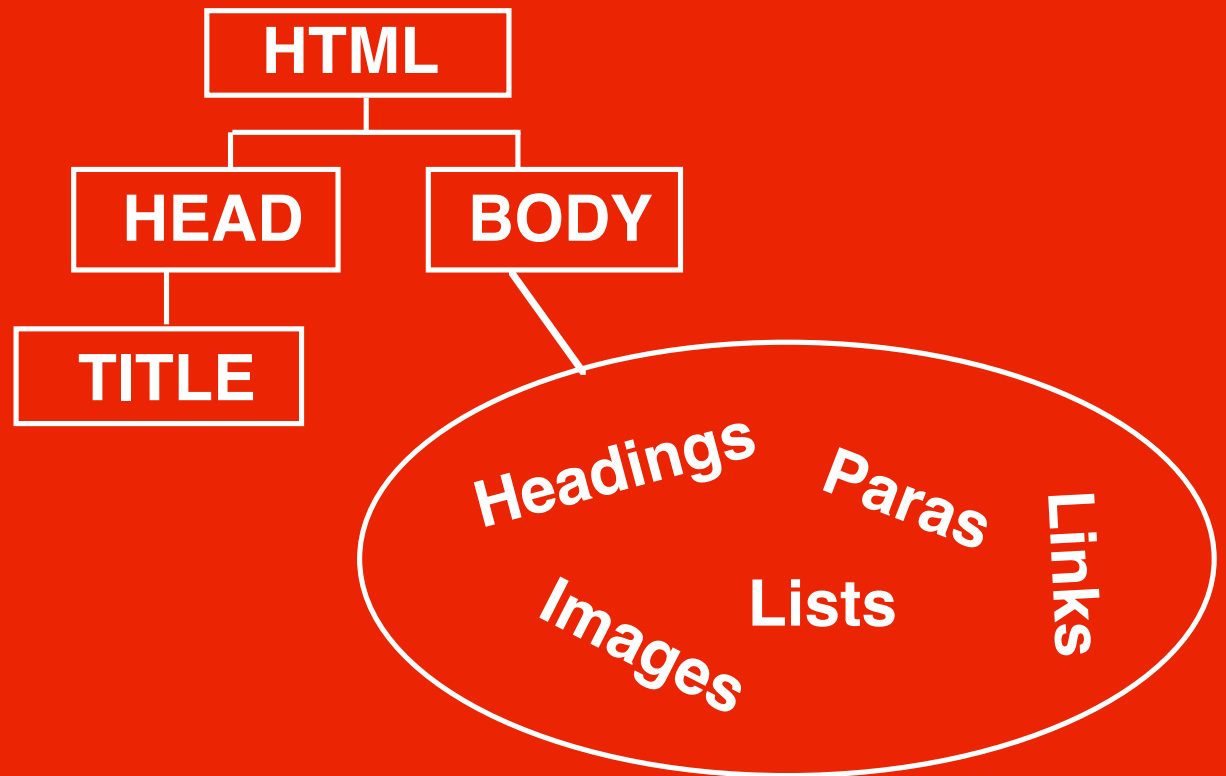

What HTML doesn't utilize ...

- No hierarchy
 - Flat structure
- No enforced structure
 - Anything can go anywhere
- No required elements
 - exception of TITLE
- Little variety of elements
 - exception of headings
- Attributes for “abstract” information

Complex SGML hierarchies

The HTML Hierarchy??

Looking forward

- Why not SGML on the Web?
- How can HTML evolve with SGML?
- Proposed HTML 3 DTD

Why not SGML on the Web?

- No common framework
- Must customize for each DTD
- Better approach
 - Use SGML if you need it, and use HTML as one of the published formats
 - Empower HTML with more features to provide a rich distribution environment

Eric's proposal

- Leave HTML as the backbone structure, but utilize more of the power of SGML
- Many features can be optional - only used if you choose to

Home Theater vs. Black & White

What would this mean for HTML?

- Provide a reasonable framework for search and linking, but no real structural constraints
- Use few required tags
- Use a simple base tag set, with optional classifications allowed

HTML Structure

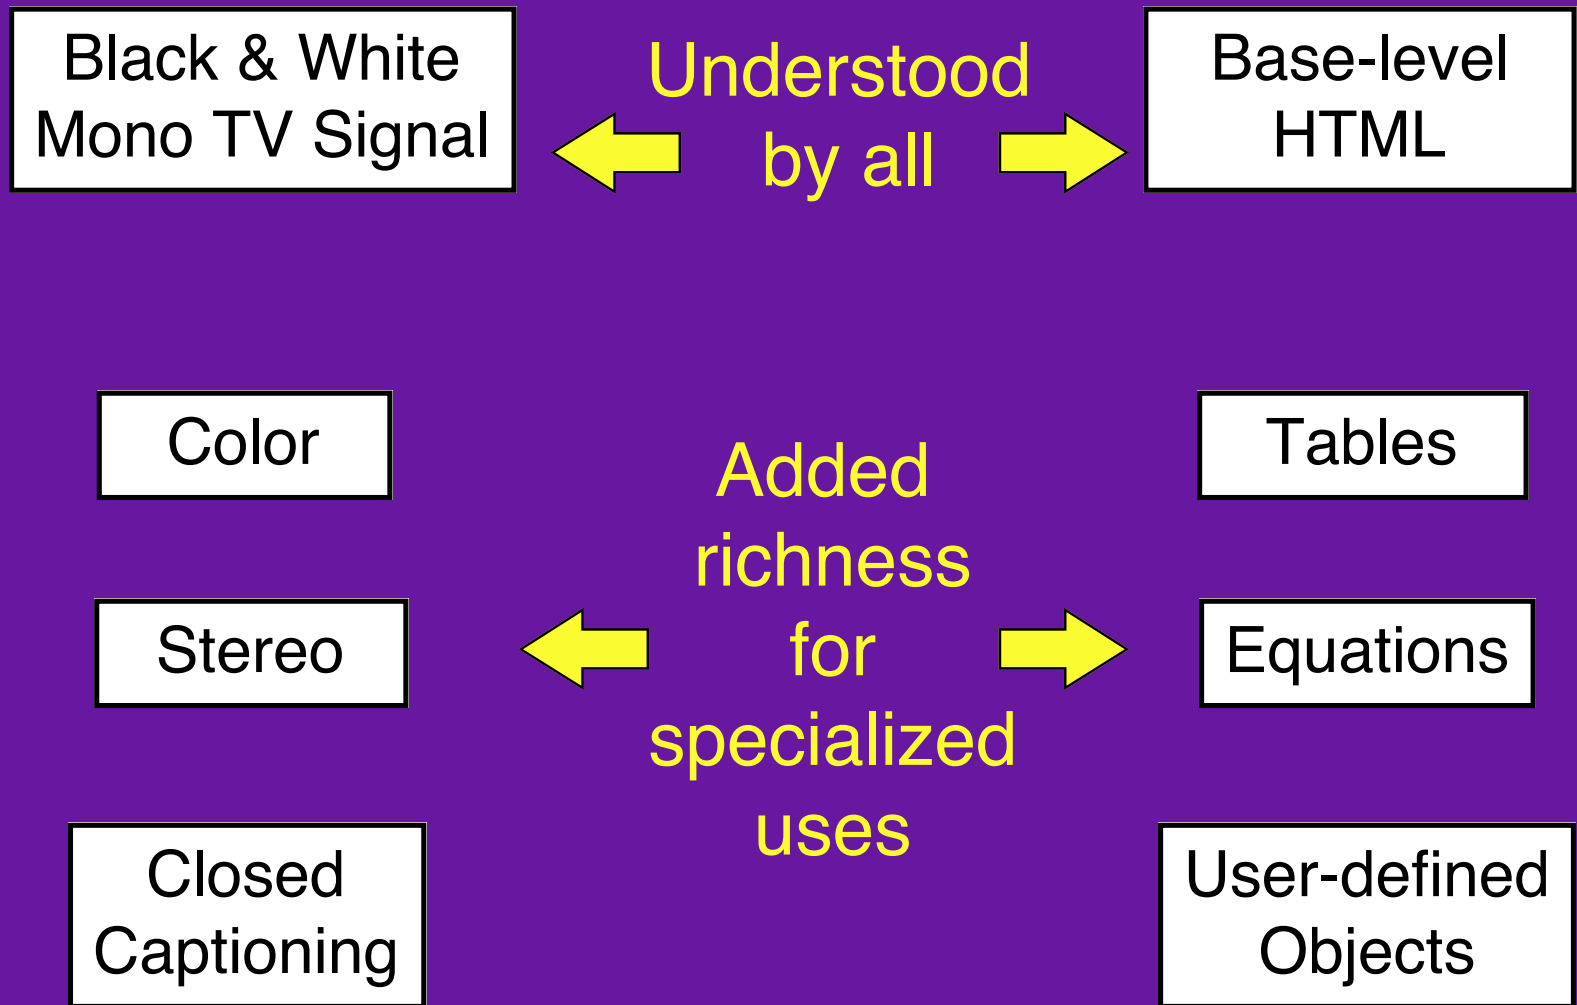

Simple, flexible

VS.

Complex, rigid

Optional layers

Classifying Elements

<p class='para'>

Para

Default

Note

Intro

Abstract

Warning

User
Defined

Added
richness
for
specialized
browsers

HTML 3 - new additions

- Documents can be more robust
 - “Class” attribute
 - Tables, math
 - Text flow around figures and tables
 - More element types

Class attribute

- Can be used to “subclass” elements

```
<p class='intro'>  
<p class='abstract'>  
<p class='summary'>  
<p class='preface'>
```

- Optional usage
- Can fit with Eric’s proposal for “scalable” usage

HTML 3 - new additions

- Many “formatting” features
 - “Style” attribute
 - Alignment
 - Banners - permanent headers
 - Needs - space required on page

Proposed formatting features

- Some features are excellent in better handling the complexity of documents
- Things to think about:
 - Do you want formatting to be permanently attached to the information?
 - In some ways are we moving towards a less flexible HTML?

Questions posed earlier ...

“If you have HTML, is there any need for SGML?”

“Is HTML a general interchange format?”

“Could HTML be the form in which I store my documents?”

The Answers ...

...lie in some additional questions to you:

**What do you need or plan to do
with your information?**

**Could you benefit from the
additional features available to
you with SGML?**

In Summary

- Many are finding themselves caught by the limitations of HTML
 - but HTML was designed to be SIMPLE
- HTML is continuously evolving, and could take advantage of more of the power of SGML
- SGML is always an option as a part of your solution

Consider SGML at the center

Remember... It's NOT a Battle

SGML and HTML do work well together

- SGML provides us with many powerful features
- HTML is just barely tapping into those possibilities
- Possible to have simplicity AND power

To find out more ...

Interleaf offers SGML training courses:

Internet 2010 - A View of the Future

Jay M. Tenenbaum
Enterprise Integration Technologies

October 1995

Societal Impact

“...ahead of the telephone and television, but behind the printing press and the motor car”

- The Economist, July 1995

Internet 2010

- **The net**

- Data dialtone

- Wireless or fiber - ubiquitous access

- Information appliances

- PCs, telephones, PDAs, TVs

- Network-aware applications and agents

- Immersive environments

- **Internet legacy**

- Flat pricing

- Openness

Societal Impact

• Freedom and Empowerment

Explosion of choices

- Where people live and work

- What they can buy

- Access to information needed to make comparisons and informed decisions

Every home a broadcast studio,
teleconferencing center, and global merchant

Bypass gatekeepers

Cross borders

Commerce

crisis = danger + opportunity

The Case For Internet Commerce

- **For Businesses**

- Sell globally

- Slash distribution costs

- Improve service

- **For Consumers**

- Unprecedented choices = wide selection, low prices

- Information to make informed decisions

- Convenience

Manufacturing - Implications

- **Mass customization**
- **Reuse of design concepts**
- **Virtual enterprises**
- **Supply-chain integration**

Higher Education

- **Universities in crisis**

- **Drivers**

Economics

Knowledge explosion

Interdisciplinary studies

Lifelong learning

Information technology

The Virtual University

- **A distributed community of scholars, students, and administrators**
- **A vast array of online resources and services**

Student services

Academic publishing

Libraries

Teaching

Research

Administration

Health Care

- **A virtual community**

Consumers

Doctors

Dentists

Specialists

Nurses

Administrators

Social Workers

Hospitals

HMOs

Laboratories

Pharmacies

Medical Libraries and
Information Services

Medical and Hospital
Suppliers

Insurers

Health Care

- **Online resources and services**

- Patient data records

- Medical information and expertise

- Collaboration/telemedicine

- Procurement services/catalogs

- Laboratory equipment

- **New roles for lawyers**

- Information providers

- Legal briefs and opinions

- Forms

- Courses

- Value-added services

- Referrals

- Indexing and organizing

- Online consulting and legal opinions

Publishing

- **Today's print-based information marketplace**

Content: writers, musicians, artists

Publishers: editing, layout, printing, promotion, distribution

Distribution: retailers, libraries, distributors, resellers

Value-added services: research, search, data analysis, reviews, copyright and royalty collection...

Publishing

- **The emerging online marketplace**

- Content creation

- Net-aware authoring and collaboration

- Publishing services

- Editors, illustrators, translators, print-on-demand, sales

- Information intermediaries

- Find, filter, personalize, aggregate, integrate, annotate, guide, consult, review, alert

- Library services

- Select, index, store, research

Publishing-Implications

- **New business models**
- **New authors - everyone**
- **New intermediaries**

Broadcasting = Narrowcasting

- **Five billion channels**
- **Every home a broadcast studio**
- **Every viewer a performer**

Societal Impact

“...ahead of the telephone and television, but behind the printing press and the motor car”

Hot New Technologies at the Fall Internet World 95
<http://www.tiac.net/users/hope/iw95.html>

Jane Dysart, Dysart & Associates
Walt Howe, Delphi Internet Associates
<http://www.delphi.com/walthowe/>
Hope Tillman, Babson College
<http://www.tiac.net/users/hope/>

Jane Dysart, Walt Howe, and Hope Tillman have selected a representative sample of innovative products from among a vast array of possible choices. Hundreds of exhibitors in over 60,000 square feet of exhibit space have showcased the most innovative products and services of today in the Internet World Exhibit Hall. The three selectors make no claim that the products selected are the best of their type but that they are a representative sample of current important trends in the Internet World. This session is designed to "package" some of the information being delivered on the exhibit floor and present it in a convenient method as a panel session.

Enabling Commerce/Tracking — CommerceNet

<http://www.commerce.net/>
William T. Wong, Enterprise Integration Technologies (VeriFone)
"CommerceNet is a non-profit consortium of organizations whose charter is to accelerate the use of the Internet for electronic commerce."

Security First Network Bank, FSB

<http://www.sfnb.com/>
"The first full-service Internet-based bank, Security First Network Bank, FSB was the first bank to license Virtual Bank Manager, which is built upon a sophisticated security architecture. Security First believes that this architecture provides, for the first time, a workable and critical element for processing secure transactions on the Internet. Security First expects to offer a full range of depositor banking services over the Internet, including mutual funds, brokerage accounts and more."

InfoMarket

<http://www.infomkt.ibm.com/>
John P. McIlraith, Strategic Alliance Manager, InfoMarket
"infoMarket allows digital publishers to plug-n-publish safely on the Internet with Cryptolopes. By using cryptolopes to transmit information, infoMarket Search solves two problems at once--protection of intellectual property and compensating authors for work that is distributed digitally."

NetCount

<http://www.netcount.com/>
Paul Grand, Chairman of the Board
"NetCount's tracking system provides detailed analysis and reporting of

website usage. Through NetCount(TM), website creators and advertisers will at last be able to make use of a universally recognized ratings system (comparable to the Nielsens) that provides precise traffic information, broken down by website, subject, page, day and hour."

Filtering — Individual, Inc.

<http://www.newspage.com/>

Russell Williams, Vice President, New Internet Ventures

"Individual's customized news products are created by an interactive, self-learning software agent (expert system) that searches a broad spectrum of electronic newswires, newspapers, and trade magazines to find the articles uniquely relevant to each client."

Eudora (Qualcomm, Inc.)

<http://www.qualcomm.com/ProdTech/quest/QuestMain.html>

Roy Ang

"Eudora saves you time in composing, managing, and responding to your e-mail separating the hot mail from the junk mail with customizable filters, and enabling you to organize your mail by personal categories."

Platform for Internet Content Selection (PICS)

<http://www.w3.org/pub/WWW/PICS/>

Rob Glaser, President CEO, Progressive Networks

"PICS is a cross-industry working group whose goal is to facilitate the development of technologies to give users of interactive media, such as the Internet, control over the kinds of material to which they and their children have access. PICS members believe that individuals, groups and businesses should have easy access to the widest possible range of content selection products, and a diversity of voluntary rating systems."

See the W3C press advisory on PICS:

http://www.w3.org/pub/WWW/PICS/951030/951030_Advisory.html

Some of the Next Generation Tools

Netscape

http://home.netscape.com/comprod/products/navigator/version_2.0/

"Netscape Navigator 2.0 is a major new release of the world's most popular Internet navigator, bringing Web exploring, email, newsgroups, chat, and FTP capabilities together in a seamlessly integrated package. It supports Live Objects and other interactive multimedia content such as Java Applets, frames, and Netscape inline plug-ins. Netscape Navigator Gold 2.0 provides all the capabilities of Netscape Navigator 2.0 plus integrated WYSIWYG document creation and publishing capabilities."

Microsoft Corporation

<http://www.microsoft.com/windows/ie/iexplorer.htm>

"To provide superior integration with today's Web pages, Internet Explorer

2.0 includes support for HTML 3.0 tables; access to Internet newsgroups; a toolbar button for instant access to the world's most powerful Web search engines; the ability to run animations using client-pull technology, and a secure environment. The addition of special Internet tokens, called "cookies," enables Web surfers to shop at their favorite Internet outlets."

Sun Microsystems

<http://java.sun.com/>

"Java (tm) is a simple, object-oriented, distributed, interpreted, robust, secure, architecture-neutral, portable, high-performance, multithreaded, dynamic, buzzword-compliant, general-purpose programming language. Java supports programming for the Internet in the form of platform-independent Java applets."

InterNotes

<http://www.lotus.com/corpcomm/334a.htm>

Angela Finney, Senior Marketing Specialist

InterNotes Web Publisher 2.0 publishes Notes documents and forms to the Web by automatically translating them into HTML. It provides full text searching returned as web links.

Web Authoring Tools

Adobe Systems (PageMill)

<http://www.adobe.com/Apps/PageMill/>

InContext Corporation

<http://www.incontext.com/>

InfoAccess (HTML Transmit)

<http://www.infoaccess.com/product/htmlpre.htm#I>

Quarterdeck Corporation (Web Author)

<http://www.qdeck.com/qdeck/demosoft/WebAuthr/>

SoftQuad (Hot Metal)

<http://www.sq.com/>

Vermeer Technologies, Inc. (FrontPage)

<http://www.vermeer.com/>

Responding to the major interest in individual web sites, exhibitors demonstrated a number of new or improved Internet web authoring tools. Each has its own strengths and features and seeks to carve out a significant share of the market.

Concluding Thoughts

Along with all the new products, there were signs of problems typical of a fast emerging technology. Standardization, necessary for compatibility across systems, requires a slow deliberative process, and the freely given participation of all concerned segments of the development community. On the other hand, the pressures of the marketplace compel competitive businesses to be the first with the newest technology, and standardization can take a back seat to "progress."

A similar problem with forces in opposition is the need to make interfaces to the Internet and web technology as easy as possible for the large numbers of new customers coming into the market, while at the same time introducing new and better capabilities. It takes just as much attention to the human factors as to the technology itself, and those who do it best can gain a great deal.

Open Market's “Commerce Architecture”

Cliff Utstein

Open Market Inc. (Booth #456)

Director, Commerce Products

Email: utstein@openmarket.com

Tel: 617-374-3768

Open Market Corporate Overview

- Founded April, '94 by David Gifford and Shikhar Ghosh
- Based in Cambridge, MA
- Satellite development center in Palo Alto, CA
- ~165 Employees
- Privately Financed
 - Greylock Venture Capital
 - Advance Publications
 - Time Warner
 - Tribune Company

Open Market Customers and Partners

Publishing

- **Time Inc.**
- **Tribune Company**
- **Advance Publications**
 - **Condé Nast**
 - **Random House**
- **Ziff Davis**
- **Lexis-Nexis**
- **Copyright Clearance Center**

Financial Services

- **Banc One**
- **First Union National Bank**
- **American Express**
- **Toronto Dominion**
- **FDC/Envoy**
- **Litle & Co.**
- **Checkfree**

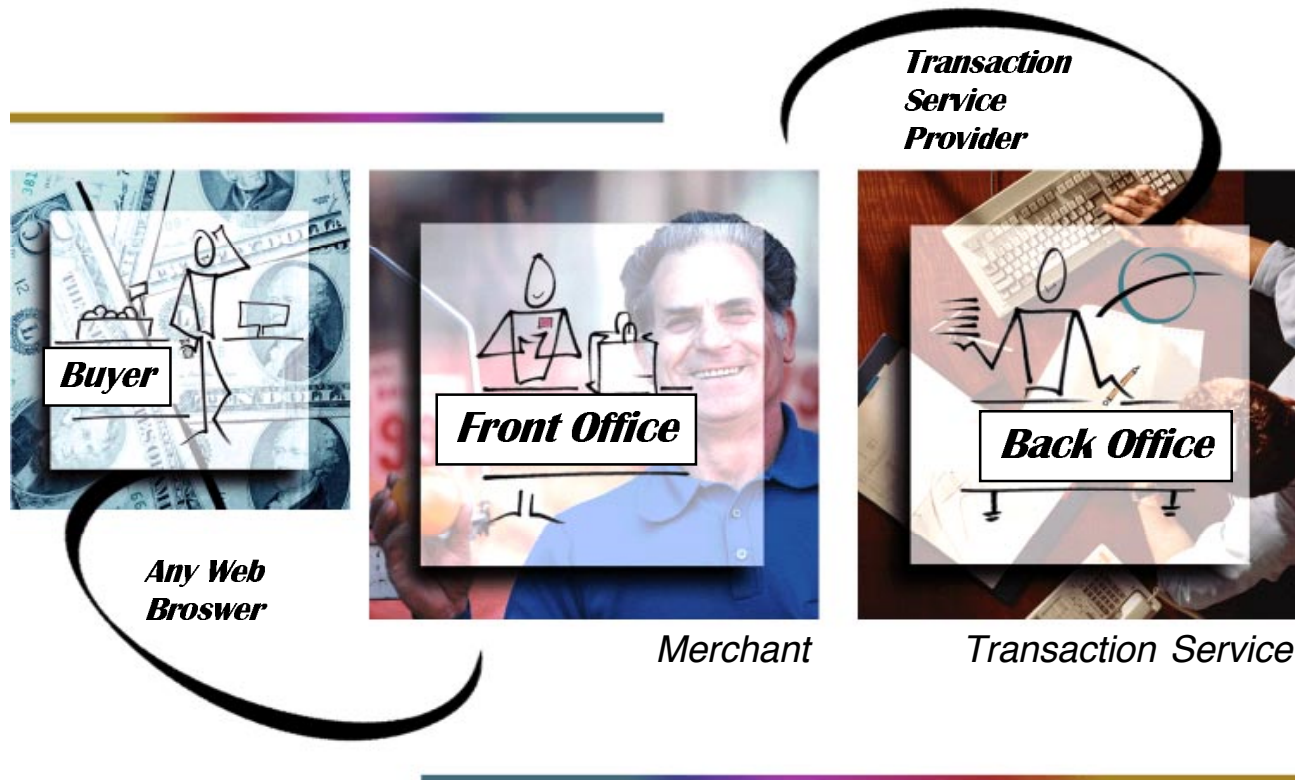

Others

- **IBM**
- **FTP Software**
- **Tandem Computers**
- **Digital Equipment Corp**
- **CyberCash**
- **Verity**
- **Personal Library SW**

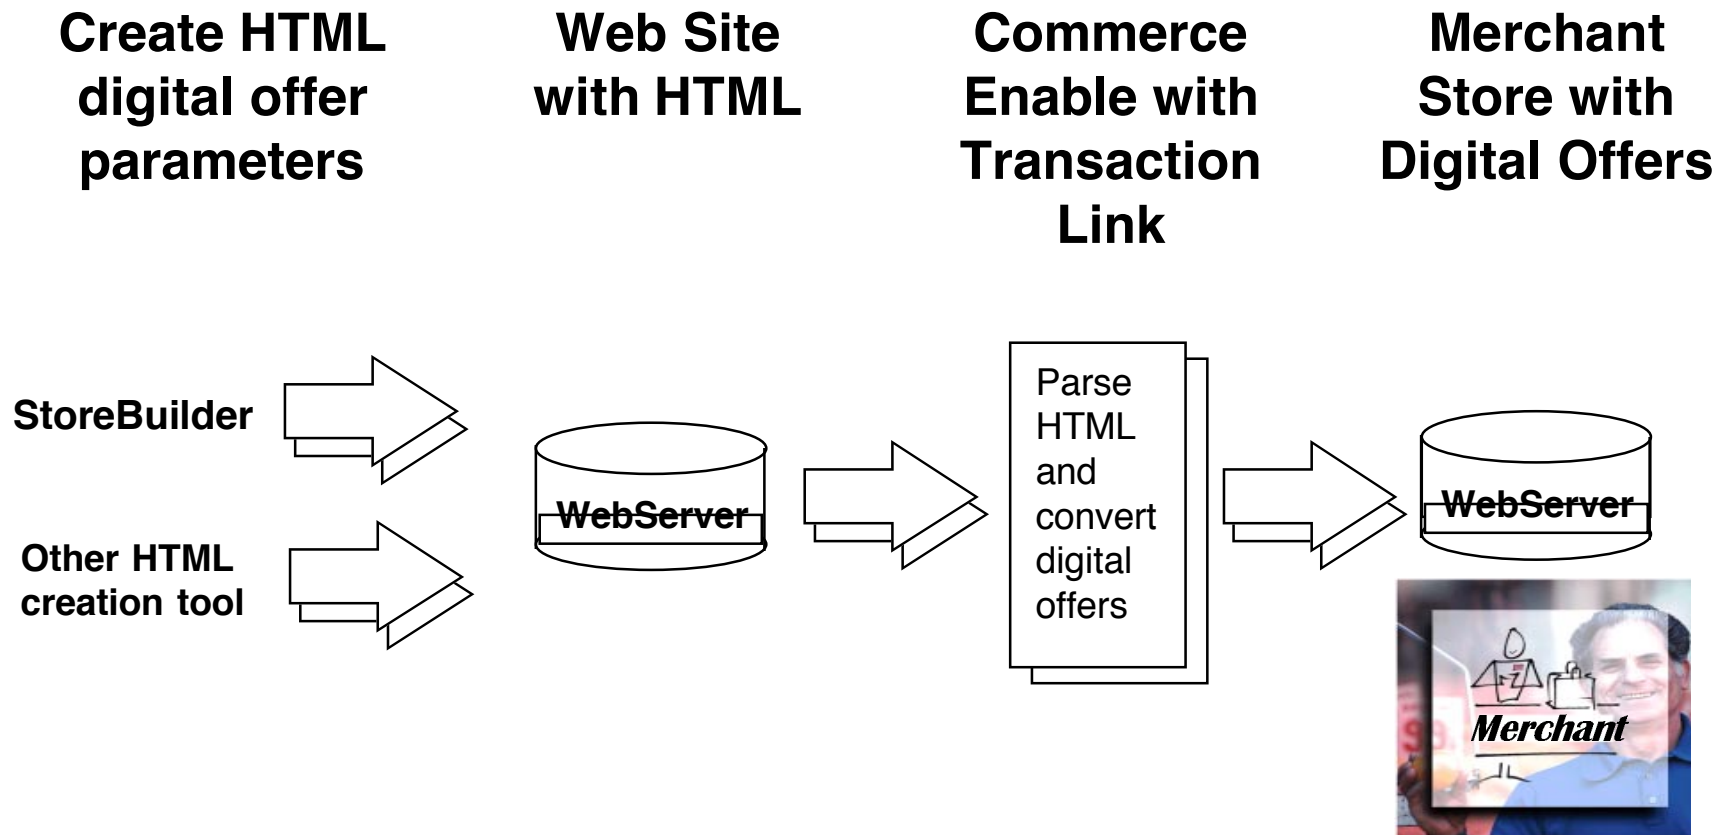

7 Requirements for Highly Effective Internet Commerce

1. Provide security for a business environment
2. Generate compelling content that attracts traffic
3. Allow on-line, order taking and payment processing
4. Fulfill both soft and hard goods
5. Facilitate customer service
6. Build customer relationships and generate reports
7. Integrate existing business systems

Open Market Commerce Architecture

How to Create a Store with Digital Offers

Commerce Architecture: Overview

- Merchants focus on their business (the *Front Office*), while the Transaction Service Provider manages the *Back Office*
- “Commerce-enable” a Web site in just a few hours
- Incorporate new *Back Office* features without additional software
- Utilize widely deployed, open, standards-based technology
- Easily scales as your business grows on the Web
- Online credit card payment and softgood fulfillment
- First product availability November 1995

Components

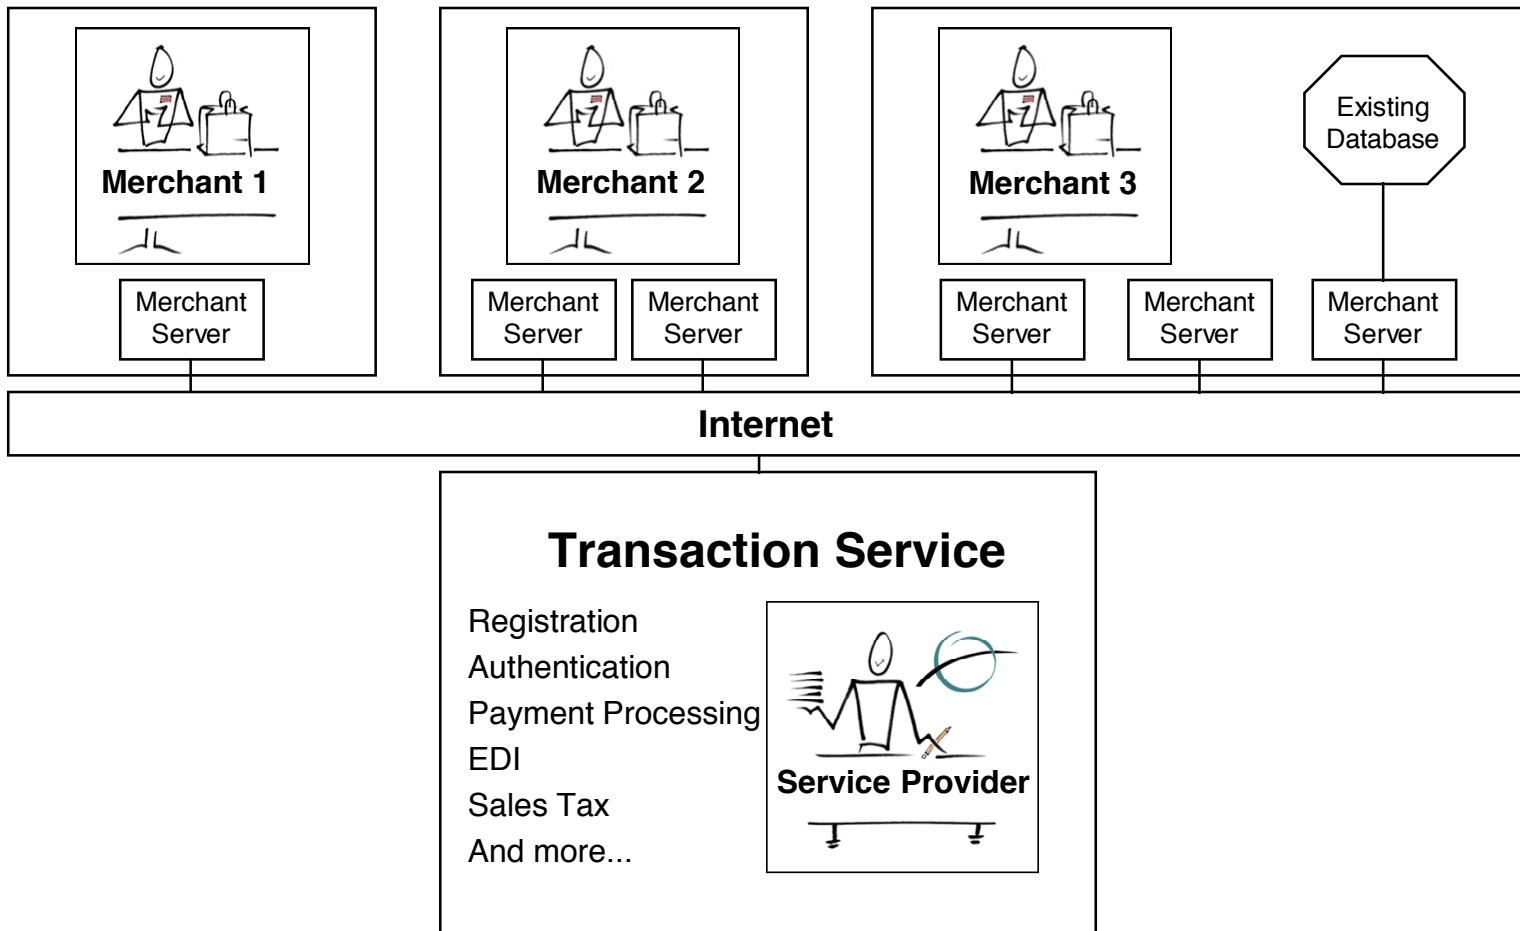

- Front Office Software Components:
 - Web server: **Secure WebServer™**
 - HTML Authoring: **StoreBuilder™**
 - Commerce Enable: **Transaction Link™**
 - Reporting: **WebReporter™**
- Back Office: **Transaction Service Provider**

“Back Office” Highlights

- Customer service automation with “SmartStatements”
- Order-taking, and credit card authorization/settlement
- Automated U.S. and Canadian sales tax calculation
- Digital Receipt generation
- Automated computation of shipping fees
- Account-based purchases with no Internet transmission of credit card information
- “Walk-in” purchases using a secure browser
- Customer customer shopping carts

Note: As new features are offered on the ICS, they're automatically available to merchants (e.g..., Cybercash payment)

Open Market's Commerce Architecture Links Distributed Content to Shared, Common Services...

...And Provides a Scalable Solution
